CASA Synthesis & Single Dish Reduction Cookbook

Beta Release Edition

Chef Editor: Steven T. Myers
CASA Project Scientist

Sous-Chef: Joe McMullin
CASA Project Manager

Do you dare to enter CASA Stadium and join battle with the Ironic Chefs?
Let us see whose cuisine reigns supreme . . .
## Contents

1 Introduction .................................................. 20
   1.1 About This Beta Release .............................. 22
      1.1.1 What’s New in Beta Patch 4 .................... 23
         1.1.1.1 Previous changes in Patch 3 ............... 25
         1.1.1.2 Previous changes introduced in Patch 2 .... 27
   1.2 CASA Basics — Information for First-Time Users .. 28
      1.2.1 Before Starting CASA ............................ 28
         1.2.1.1 Environment Variables ..................... 29
         1.2.1.2 Where is CASA? ............................ 29
      1.2.2 Starting CASA ..................................... 30
      1.2.3 Ending CASA ....................................... 30
      1.2.4 What happens if something goes wrong? .......... 30
      1.2.5 Aborting CASA execution ......................... 31
      1.2.6 What happens if CASA crashes? .................. 31
      1.2.7 Python Basics for CASA ......................... 32
         1.2.7.1 Variables .................................... 32
         1.2.7.2 Lists and Ranges ............................ 32
         1.2.7.3 Indexes ...................................... 33
         1.2.7.4 Indentation .................................. 33
         1.2.7.5 System shell access ......................... 33
         1.2.7.6 Executing Python scripts .................. 34
      1.2.8 Getting Help in CASA ............................. 34
         1.2.8.1 TAB key ..................................... 34
         1.2.8.2 help <taskname> .............................. 35
         1.2.8.3 help and PAGER .............................. 37
         1.2.8.4 help par.<parameter> ....................... 37
         1.2.8.5 Python help .................................. 37
   1.3 Tasks and Tools in CASA .............................. 38
      1.3.1 What Tasks are Available? ....................... 39
      1.3.2 Running Tasks and Tools ......................... 42
         1.3.2.1 Aborting Synchronous Tasks ................. 44
      1.3.3 Getting Return Values ............................ 44
      1.3.4 Running Tasks Asynchronously ................... 45
         1.3.4.1 Monitoring Asynchronous Tasks .............. 45
1.5.6.2 Image statistics ......................................................... 73
1.5.6.3 Moments of an Image Cube ........................................ 73
1.5.6.4 Image math .......................................................... 73
1.5.6.5 Regridding an Image .................................................. 73
1.5.6.6 Displaying Images ................................................... 74
1.5.7 Getting data and images out of CASA ............................ 74

2 Visibility Data Import, Export, and Selection .......................... 75
2.1 CASA Measurement Sets ................................................ 76
2.1.1 Under the Hood: Structure of the Measurement Set .............. 76
2.2 Data Import and Export .................................................. 79
2.2.1 UVFITS Import and Export ........................................... 79
2.2.1.1 Import using importuvfits ...................................... 80
2.2.1.2 Export using exportuvfits ....................................... 80
2.2.2 VLA: Filling data from archive format (importvla) .............. 81
2.2.2.1 Parameter applysys ............................................... 82
2.2.2.2 Parameter bandname ............................................. 83
2.2.2.3 Parameter frequencytol ......................................... 83
2.2.2.4 Parameter project .................................................. 83
2.2.2.5 Parameters starttime and stoptime ............................ 84
2.2.2.6 Parameter autocorr ................................................ 84
2.2.2.7 Parameter antnames scheme .................................... 84
2.2.3 ALMA: Filling ALMA Science Data Model (ASDM) observations ....... 84
2.3 Summarizing your MS (listobs) ........................................ 86
2.4 Listing and manipulating MS metadata (vishead) .................... 89
2.5 Concatenating multiple datasets (concat) ............................ 89
2.6 Data Selection ........................................................... 91
2.6.1 General selection syntax .............................................. 91
2.6.1.1 String Matching ................................................... 92
2.6.2 The field Parameter ................................................... 93
2.6.3 The spw Parameter .................................................... 94
2.6.3.1 Channel selection in the spw parameter ....................... 95
2.6.4 The selectdata Parameters .......................................... 96
2.6.4.1 The antenna Parameter ........................................... 96
2.6.4.2 The scan Parameter ............................................... 98
2.6.4.3 The timerange Parameter ....................................... 98
2.6.4.4 The uvrangle Parameter ......................................... 99
2.6.4.5 The msselect Parameter ......................................... 100

3 Data Examination and Editing ............................................. 101
3.1 Plotting and Flagging Visibility Data in CASA ....................... 101
3.2 Managing flag versions with flagmanager ............................ 102
3.3 Flagging auto-correlations with flagautocorr ....................... 103
3.4 X-Y Plotting and Editing of the Data ................................. 103
3.4.1 GUI Plot Control ..................................................... 107
3.4.2 The selectplot Parameters .................................................. 108
3.4.3 Plot Control Parameters ..................................................... 109
  3.4.3.1 iteration ............................................................................. 109
  3.4.3.2 overplot ............................................................................. 109
  3.4.3.3 plotrange .......................................................................... 110
  3.4.3.4 plotsymbol ........................................................................ 111
  3.4.3.5 showflags .......................................................................... 112
  3.4.3.6 subplot .............................................................................. 112
3.4.4 Averaging in plotxy ................................................................. 113
3.4.5 Interactive Flagging in plotxy ................................................. 114
3.4.6 Flag extension in plotxy .......................................................... 115
3.4.7 Setting rest frequencies in plotxy ............................................ 116
3.4.8 Printing from plotxy ............................................................... 117
3.4.9 Exiting plotxy .......................................................................... 118
3.4.10 Example session using plotxy ............................................... 118
3.5 Non-Interactive Flagging using flagdata ..................................... 121
  3.5.1 Flag Antenna/Channels ......................................................... 122
    3.5.1.1 Manual flagging and clipping in flagdata ......................... 123
    3.5.1.2 Flagging the beginning of scans ...................................... 124
3.6 Browse the Data ........................................................................ 124
3.7 Plotting antenna positions (plotants) ......................................... 126
3.8 MS Plotting and Editing using casaplotms .................................. 127
3.9 Examples of Data Display and Flagging ..................................... 127

4 Synthesis Calibration .................................................................. 128
4.1 Calibration Tasks ...................................................................... 128
4.2 The Calibration Process — Outline and Philosophy .................. 129
  4.2.1 The Philosophy of Calibration in CASA .............................. 131
  4.2.2 Keeping Track of Calibration Tables ................................ 132
  4.2.3 The Calibration of VLA data in CASA ................................. 133
4.3 Preparing for Calibration .......................................................... 134
  4.3.1 System Temperature Correction ......................................... 134
  4.3.2 Antenna Gain-Elevation Curve Calibration ........................... 135
  4.3.3 Atmospheric Optical Depth Correction ............................... 136
    4.3.3.1 Determining opacity corrections for VLA data ............... 136
  4.3.4 Setting the Flux Density Scale using (setjy) ......................... 137
    4.3.4.1 Using Calibration Models for Resolved Sources ............ 139
  4.3.5 Other a priori Calibrations and Corrections ......................... 141
4.4 Solving for Calibration — Bandpass, Gain, Polarization ............. 141
  4.4.1 Common Calibration Solver Parameters ............................. 141
    4.4.1.1 Parameters for Specification : vis and caltable ............. 142
    4.4.1.2 Selection: field, spw, and selectdata ............................ 142
    4.4.1.3 Prior Calibration and Correction: parang, gaincurve and opacity 143
    4.4.1.4 Previous Calibration: gaintable, gainfield, interp and spwmap ... 143
    4.4.1.5 Solving: solint, combine, preavg, refant, minblperant, minsnr ... 145
5.2.5.1 Mode mfs
5.2.5.2 Mode channel
5.2.5.3 Mode frequency
5.2.5.4 Mode velocity
5.2.5.5 Sub-parameter interpolation
5.2.6 Parameter phasecenter
5.2.7 Parameter restfreq
5.2.8 Parameter spw
5.2.9 Parameter stokes
5.2.10 Parameter uvtaper
5.2.11 Parameter weighting
5.2.11.1 'natural' weighting
5.2.11.2 'uniform' weighting
5.2.11.3 'superuniform' weighting
5.2.11.4 'radial' weighting
5.2.11.5 'briggs' weighting
5.2.11.6 'briggsabs' weighting
5.2.12 Parameter vis
5.2.13 Primary beams in imaging
5.3 Deconvolution using CLEAN (clean)
5.3.1 Parameter psfmode
5.3.1.1 The clark algorithm
5.3.1.2 The hogbom algorithm
5.3.1.3 The clarkstokes algorithm
5.3.2 The multiscale parameter
5.3.3 Parameter gain
5.3.4 Parameter imagermode
5.3.4.1 Sub-parameter cyclefactor
5.3.4.2 Sub-parameter cyclespeedup
5.3.4.3 Sub-parameter ftmachine
5.3.4.4 Sub-parameter mosweight
5.3.4.5 Sub-parameter scaletype
5.3.4.6 The threshold revisited
5.3.5 Parameter interactive
5.3.6 Parameter mask
5.3.6.1 Setting clean boxes
5.3.6.2 Using clean box files
5.3.6.3 Using clean mask images
5.3.6.4 Using region files
5.3.7 Parameter minpb
5.3.8 Parameter modelimage
5.3.9 Parameter niter
5.3.10 Parameter pbcor
5.3.11 Parameter restoringbeam
5.3.12 Parameter threshold
6.11.1 FITS Image Export (exportfits) ............................................. 252
6.11.2 FITS Image Import (importfits) ........................................... 252
6.12 Using the CASA Toolkit for Image Analysis .................................. 253
6.13 Examples of CASA Image Analysis ............................................ 255

7 Visualization With The CASA Viewer ............................................. 256
7.1 Starting the viewer .................................................................. 256
7.1.1 Running the CASA viewer outside casapy ................................. 258
7.2 The viewer GUI ...................................................................... 259
7.2.1 The Viewer Display Panel .................................................... 259
7.2.2 Saving and Restoring Display Panel State ................................. 263
7.2.3 Region Selection and Positioning .......................................... 263
7.2.4 The Load Data Panel ............................................................ 264
7.2.4.1 Registered vs. Open Datasets ........................................... 266
7.3 Viewing Images ..................................................................... 266
7.3.1 Viewing a raster map .......................................................... 266
7.3.1.1 Raster Image — Basic Settings ........................................ 268
7.3.1.2 Raster Image — Other Settings ........................................ 270
7.3.2 Viewing a contour map ........................................................ 271
7.3.3 Overlay contours on a raster map ......................................... 272
7.3.4 Spectral Profile Plotting ....................................................... 273
7.3.5 Managing and Saving Regions ............................................ 273
7.3.6 Adjusting Canvas Parameters/Multi-panel displays .................. 275
7.3.6.1 Setting up multi-panel displays ....................................... 277
7.3.6.2 Background Color ......................................................... 277
7.4 Viewing Measurement Sets ....................................................... 277
7.4.1 Data Display Options Panel for Measurement Sets .................. 278
7.4.1.1 MS Options — Basic Settings ......................................... 279
7.4.1.2 MS Options— MS and Visibility Selections ....................... 279
7.4.1.3 MS Options — Display Axes ........................................... 281
7.4.1.4 MS Options — Flagging Options ..................................... 282
7.4.1.5 MS Options— Advanced ................................................ 285
7.4.1.6 MS Options — Apply Button ............................................ 286
7.5 Printing from the Viewer ........................................................... 286

D.11 Executing Python scripts
D.12 How do I exit from CASA?

# Appendix: The Measurement Equation and Calibration

E.1 The HBS Measurement Equation
E.2 General Calibrator Mechanics

# Appendix: Annotated Example Scripts

F.1 NGC 5921 — VLA red-shifted HI emission
F.2 Jupiter — VLA continuum polarization
F.3 BIMA Mosaic Spectral Imaging

# Appendix: CASA Dictionaries

G.1 AIPS – CASA dictionary
G.2 MIRIAD – CASA dictionary
G.3 CLIC – CASA dictionary

# Appendix: Writing Tasks in CASA

H.1 The XML file
H.2 The `task_yourtask.py` file
H.3 Example: The `clean` task
  H.3.1 File `clean.xml`
H.3.2  File task_clean.py  ................................................. 498
## List of Tables

2.1 Common MS Columns ........................................ 78
2.2 Commonly accessed MAIN Table columns .................. 79
4.1 Recognized Flux Density Calibrators ...................... 138
G.1 MIRIAD – CASA dictionary ................................. 474
G.2 CLIC–CASA dictionary ...................................... 475
List of Figures

1.1 Screen shot of the default CASA inputs for task clean. .......................... 53
1.2 The clean inputs after setting values away from their defaults (blue text). Note that some of the boldface ones have opened up new dependent sub-parameters (indented and green). ......................................................... 54
1.3 The clean inputs where one parameter has been set to an invalid value. This is drawn in red to draw attention to the problem. This hapless user probably confused the 'hogbom' clean algorithm with Harry Potter. ................................. 55
1.4 The CASA Logger GUI window under Linux. Note that under MacOSX a stripped down logger will instead appear as a Console. ......................................................... 58
1.5 Using the Search facility in the casalogger. Here we have specified the string 'plotted' and it has highlighted all instances in green. ................................. 59
1.6 Using the casalogger Filter facility. The log output can be sorted by Priority, Time, Origin, and Message. In this example we are filtering by Origin using 'clean', and it now shows all the log output from the clean task. ................................. 60
1.7 CASA Logger - Insert facility: The log output can be augmented by adding notes or comments during the reduction. The file should then be saved to disk to retain these changes. ................................................. 59
1.8 Flow chart of the data processing operations that a general user will carry out in an end-to-end CASA reduction session. ......................................................... 65

2.1 The contents of a Measurement Set. These tables compose a Measurement Set named ngc5921.demo.ms on disk. This display is obtained by using the File:Open menu in browsetable and left double-clicking on the ngc5921.demo.ms directory. ....... 77

3.1 The plotxy plotter, showing the Jupiter data versus uv-distance. You can see bad data in this plot. The bottom set of buttons on the lower left are: 1,2,3) Home, Back, and Forward. Click to navigate between previously defined views (akin to web navigation). 4) Pan. Click and drag to pan to a new position. 5) Zoom. Click to define a rectangular region for zooming. 6) Subplot Configuration. Click to configure the parameters of the subplot and spaces for the figures. 7) Save. Click to launch a file save dialog box. The upper set of buttons in the lower left are: 1) Mark Region. Press this to begin marking regions (rather than zooming or panning). 2,3,4) Flag, Unflag, Locate. Click on these to flag, unflag, or list the data within the marked regions. 5) Next. Click to move to the next in a series of iterated plots. Finally, the cursor readout is on the bottom right. ............ 104
3.2 The plotxy iteration plot. The first set of plots from the example in §3.4.3.1 with
iteration='antenna'. Each time you press the Next button, you get the next
series of plots.

3.3 Multi-panel display of visibility versus channel (top), antenna array configuration
(bottom left) and the resulting uv coverage (bottom right). The commands to
make these three panels respectively are: 1) plotxy('ngc5921.ms', xaxis='channel',
datacolumn='data', field='0', subplot=211, plotcolor='', plotsymbol='go')
2) plotxy('ngc5921.ms', xaxis='x', field='0', subplot=223, plotsymbol='r.')
3) plotxy('ngc5921.ms', xaxis='u', yaxis='v', field='0', subplot=224, plotsymbol='b,',figfile='ngc5921 mult.png')

3.4 Plot of amplitude versus uv distance, before (left) and after (right) flagging two
marked regions. The call was: plotxy(vis='ngc5921.ms',xaxis='uvdist', field='1445*').

3.5 flagdata: Example showing before and after displays using a selection of one anten-
a and a range of channels. Note that each invocation of the flagdata task repres-
ts a cumulative selection, i.e., running antenna='0' will flag all data with antenna
0, while antenna='0', spw='0:10 15' will flag only those channels on antenna 0.

3.6 flagdata: Flagging example using the clip facility.

3.7 browsetable: The browser displays the main table within a frame. You can scroll
through the data (x=columns of the MAIN table, and y=the rows) or select a specific
page or row as desired. By default, 1000 rows of the table are loaded at a time, but
you can step through the MS in batches.

3.8 browsetable: You can use the tab for Table Keywords to look at other tables within
an MS. You can then double-click on a table to view its contents.

3.9 browsetable: Viewing the SOURCE table of the MS.

4.1 Flow chart of synthesis calibration operations. Not shown are use of table manipu-
lation and plotting tasks accum, plotcal, and smoothcal (see Figure 4.2).

4.2 Chart of the table flow during calibration. The parameter names for input or output
of the tasks are shown on the connectors. Note that from the output solver through
the accumulator only a single calibration type (e.g. 'B', 'G') can be smoothed,
interpolated or accumulated at a time. The final set of cumulative calibration tables
of all types are then input to applycal as shown in Figure 4.1.

4.3 Display of the amplitude (upper) and phase (lower) gain solutions for all antennas
and polarizations in the ngc5921 post-fluxscale table.

4.4 Display of the amplitude (upper), phase (middle), and signal-to-noise ratio (lower)
of the bandpass 'B' solutions for antenna='0' and both polarizations for ngc5921.
Note the falloff of the SNR at the band edges in the lower panel.

4.5 Display of the amplitude of the bandpass 'B' solutions. Iteration over antennas was
turned on using iteration='antenna'. The first page is shown. The user would
use the Next button to advance to the next set of antennas.

4.6 The 'amp' of gain solutions for NGC4826 before (top) and after (bottom) smoothing
with a 7200 sec smoothtime and smoothtype='mean'. Note that the first solution
is in a different spw and on a different source, and is not smoothed together with the
subsequent solutions.
4.7 The ‘phase’ of gain solutions for NGC4826 before (top) and after (bottom) ‘linear’ interpolation onto a 20 sec accumtime grid. The first scan was 3C273 in spw='0' while the calibrator scans on 1331+305 were in spw='1'. The use of spwmap was necessary to transfer the interpolation correctly onto the NGC4826 scans.

4.8 The final ‘amp’ (top) and ‘phase’ (bottom) of the self-calibration gain solutions for Jupiter. An initial phase calibration on 10s solint was followed by an incremental gain solution on each scan. These were accumulated into the cumulative solution shown here.

4.9 The final ‘amp’ versus ‘uvdist’ plot of the self-calibrated Jupiter data, as shown in plotxy. The ‘RR LL’ correlations are selected. No outliers that need flagging are seen.

4.10 Use of plotxy to display corrected data (red and blue points) and uv model fit data (green circles).

5.1 Close-up of the top of the interactive clean window. Note the boxes at the left (where the iterations, cycles, and threshold can be changed), the buttons that control add/erase, the application of mask to channels, and whether to stop, complete, or continue cleaning, and the row of Mouse-button tool assignment icons.

5.2 Screen-shots of the interactive clean window during deconvolution of the VLA 6m Jupiter dataset. We start from the calibrated data, but before any self-calibration. In the initial stage (left), the window pops up and you can see it dominated by a bright source in the center. Next (right), we zoom in and draw a box around this emission. We have also at this stage dismissed the tape deck and Position Tracking parts of the display (§ 7.2.1) as they are not used here. We have also changed the iterations to 30 for this boxed clean. We will now hit the Next Action Continue Cleaning button (the green clockwise arrow) to start cleaning.

5.3 We continue in our interactive cleaning of Jupiter from where Figure 5.2 left off. In the first (left) panel, we have cleaned 30 iterations in the region previously marked, and are zoomed in again ready to extend the mask to pick up the newly revealed emission. Next (right), we have used the Polygon tool to redraw the mask around the emission, and are ready to Continue Cleaning for another 100 iterations.

5.4 We continue in our interactive cleaning of Jupiter from where Figure 5.3 left off. In the first (left) panel, it has cleaned deeper, and we come back and zoom in to see that our current mask is good and we should clean further. We change npercycle to 500 (from 100) in the box at upper right of the window. In the final panel (right), we see the results after this clean. The residuals are such that we should terminate the clean using the red X button and use our model for self-calibration.

5.5 After clean and self-calibration using the intensity image, we arrive at the final polarization image of Jupiter. Shown in the viewer superimposed on the intensity raster is the linear polarization intensity (green contours) and linear polarization B-vectors (vectors). The color of the contours and the sampling and rotation by 90 degrees of the vectors was set in the Display Options panel. A LEL expression was used in the Load Data panel to mask the vectors on the polarized intensity.
5.6 Screen-shot of the interactive clean window during deconvolution of the NGC5921 spectral line dataset. Note where we have selected the mask to apply to the displayed Plane rather than All Channels. We have just used the Polygon tool to draw a mask region around the emission in this channel, which will apply to this channel only.

6.1 NGC2403 VLA moment zero (left) and NGC4826 BIMA moment one (right) images as shown in the viewer.

7.1 The Viewer Display Panel (left) and Data Display Options (right) panels that appear when the viewer is called with the image cube from NGC5921 (viewer(’ngc5921.usecase.clean.image’))

The initial display is of the first channel of the cube.

7.2 The Viewer Display Panel (left) and Data Display Options (right) panels that appear when the viewer is called with the NGC5921 Measurement Set (viewer(’ngc5921.usecase.ms’)).

7.3 The display panel’s Main Toolbar appears directly below the menus and contains 'shortcut' buttons for most of the frequently-used menu items.

7.4 The 'Mouse Tool' Bar allows you to assign separate mouse buttons to tools you control with the mouse within the image display area. Initially, zooming, color adjustment, and rectangular regions are assigned to the left, middle and right mouse buttons, respectively.

7.5 The Load Data - Viewer panel that appears if you open the viewer without any infile specified, or if you use the Data:Open menu or Open icon. You can see the images and MS available in your current directory, and the options for loading them.

7.6 The Load Data - Viewer panel as it appears if you select an image. You can see all options are available to load the image as a Raster Image, Contour Map, Vector Map, or Marker Map. In this example, clicking on the Raster Image button would bring up the displays shown in Figure 7.1.

7.7 The Basic Settings category of the Data Display Options panel as it appears if you load the image as a Raster Image. This is a zoom-in for the data displayed in Figure 7.1.

7.8 Example curves for scaling power cycles.

7.9 The Viewer Display Panel (left) and Data Display Options panel (right) after choosing Contour Map from the Load Data panel. The image shown is for channel 11 of the NGC5921 cube, selected using the Animator tape deck, and zoomed in using the tool bar icon. Note the different options in the open Basic Settings category of the Data Display Options panel.

7.10 The Viewer Display Panel (left) and Data Display Options panel (right) after overlaying a Contour Map of velocity on a Raster Image of intensity. The image shown is for the moments of the NGC5921 cube, zoomed in using the tool bar icon. The tab for the contour plot is open in the Data Display Options panel.

7.11 The Image Profile panel that appears if you use the Tools:Spectral Profile menu, and then use the rectangle or polygon tool to select a region in the image. You can also use the crosshair to get the profile at a single position in the image. The profile will change to track movements of the region or crosshair if moved by dragging with the mouse.
7.12 The **Region Manager** panel that appears if you select the **Tools:Region Manager** menu item. ......................... 275
7.13 Selecting an image region with the polygon tool. ................................................................. 276
7.14 A multi-panel display set up through the **Viewer Canvas Manager**. ................................. 277
7.15 The **Load Data - Viewer** panel as it appears if you select an MS. The only option available is to load this as a **Raster Image**. In this example, clicking on the **Raster Image** button would bring up the displays shown in Figure 7.2] ............................. 278
7.16 The MS for NGC4826 BIMA observations has been loaded into the viewer. We see the first of the **spw** in the Display Panel, and have opened up **MS and Visibility Selections** in the **Data Display Options** panel. The display panel raster is not full of visibilities because **spw 0** is continuum and was only observed for the first few scans. This is a case where the different spectral windows have different numbers of channels also. ................................. 279
7.17 The MS for NGC4826 from Figure 7.16, now with the **Display Axes** open in the **Data Display Options** panel. By default, **channels** are on the **Animation Axis** and thus in the tapedeck, while **spectral window** and **polarization** are on the **Display Axes** sliders. .................................................. 280
7.18 The MS for NGC4826, continuing from Figure 7.17. We have now put **spectral window** on the **Animation Axis** and used the tapedeck to step to **spw 2**, where we see the data from the rest of the scans. Now **channels** is on a **Display Axes** slider, which has been dragged to show **Channel 33**. .................................................. 281
7.19 Setting up to print to a file. The background color has been set to **white**, the line width to 2, and the print resolution to 600 dpi (for an postscript plot). To make the plot, use the **Save** button on the **Viewer Print Manager** panel (positioned in the figure in the upper right) and select a format with the drop-down, or use the **Print** button to send directly to a printer. ............................................ 287

A.1 Wiring diagram for the SDtask **sdcal**. The stages of processing within the task are shown, along with the parameters that control them. ................................. 293
A.2 Total power data display using **sdtpimaging**, with **calmode='baseline'**. The top panel shows uncalibrated data versus row numbers. The middle panel shows baseline fitting of each scan (only shown here the last scan). The bottom panel shows the calibrated (baseline subtracted) data. ................................. 340
A.3 Multi-panel display of the scantable. There are two plots per scan indicating the _psr (reference position data) and the _ps (source data). ................................. 357
A.4 Two panel plot of the calibrated spectra. The GBT data has a separate scan for the SOURCRE and REFERENCE positions so scans 20,21,22 and 23 result in these two spectra. ................................. 358
A.5 Calibrated spectrum with a line at zero (using histograms). ................................. 358
A.6 FLS3a HI emission. The display illustrates the visualization of the data cube (left) and the profile display of the cube at the cursor location (right); the Tools menu of the Viewer Display Panel has a **Spectral Profile** button which brings up this display. By default, it grabs the left-mouse button. Pressing down the button and moving in the display will show the profile variations. ................................. 362
Chapter 1

Introduction

This document describes how to calibrate and image interferometric and single-dish radio astronomical data using the CASA (Common Astronomy Software Application) package. CASA is a suite of astronomical data reduction tools and tasks that can be run via the IPython interface to Python. CASA is being developed in order to fulfill the data post-processing requirements of the ALMA and EVLA projects, but also provides basic and advanced capabilities useful for the analysis of data from other radio, millimeter, and submillimeter telescopes.

You have in your hands the Beta Release of CASA. This means that there are a number of caveats and limitations for the use of this package. See §1.1 below for more information, and pay heed to the numerous BETA ALERTs placed throughout this cookbook. You can expect regular updates and patches, as well as increasing functionality. But you can also expect interface changes. The goals of this Beta Release are to get the package out into the hands of real users so you can take it for a spin. Please knock it about a bit, but remember it is not a polished, finished product. Beware!

This cookbook is a task-based walk-through of interferometric data reduction and analysis. In CASA, tasks represent the more streamlined operations that a typical user would carry out. The idea for having tasks is that they are simple to use, provide a more familiar interface, and are easy to learn for most astronomers who are familiar with radio interferometric data reduction (and hopefully for novice users as well). In CASA, the tools provide the full capability of the package, and are the atomic functions that form the basis of data reduction. These tools augment the tasks, or fill in gaps left by tasks that are under development but not yet available. See the CASA User Reference Manual for more details on the tools. Note that in most cases, the tasks are Python interface scripts to the tools, but with specific, limited access to them and a standardized interface for parameter setting. The tasks and tools can be used together to carry out more advanced data reduction operations.

For the moment, the audience is assumed to have some basic grasp of the fundamentals of synthesis imaging, so details of how a radio interferometer or telescope works and why the data needs to
undergo calibration in order to make synthesis images are left to other documentation — a good place to start might be Synthesis Imaging in Radio Astronomy II (1999, ASP Conference Series Vol. 180, eds. Taylor, Carilli & Perley).

This cookbook is broken down by the main phases of data analysis:

- data import, export, and selection (Chapter 2),
- examination and flagging of data (Chapter 3),
- interferometric calibration (Chapter 4),
- interferometric imaging (Chapter 5),
- image analysis (Chapter 6), and
- data and image visualization (Chapter 7).

**BETA ALERT:** For the Beta Release, there are also special chapters in the Appendix on

- single dish data analysis (Chapter A), and
- simulation (Chapter B).

These are included for users that will be doing EVLA and ALMA telescope commissioning and software development. They will become part of the main cookbook in later releases.

The general appendices provide more details on what’s happening under the hood of CASA, as well as supplementary material on tasks, scripts, and relating CASA to other packages. These appendices include:

- obtaining and installing CASA (Appendix C),
- more details about Python and CASA (Appendix D),
- a discussion of the Hamaker-Bregman-Sault Measurement Equation (Appendix E),
- annotated scripts for typical data reduction cases (Appendix F), and
- CASA dictionaries to AIPS, MIRIAD, and CLIC (Appendix G).
- Writing your own CASA Task (Appendix H).

The CASA User Documentation includes:

- **CASA Synthesis & Single Dish Reduction Cookbook** — this document, a task-based data analysis walk-through and instructions;
- **CASA in-line help** — accessed using `help` in the `casapy` interface;
• The CASA Toolkit Reference Manual — details on a specific task or tool does and how to use it.

• The CASA Task Reference Manual — the information from the inline help and task documentation, available online in HTML.

The CASA home page can be found at:

http://casa.nrao.edu

From there you can find documentation and assistance for the use of the package, including the User Documentation. You will also find information on how to obtain the latest release and receive user support.

1.1 About This Beta Release

Currently, CASA is in the Beta Release stage. This means that much, but not all, of the eventual functionality is available. Furthermore, the package is still under development, and some features might change in future releases. This should be taken into account as users begin to learn the package. We will do our best to point out commands, tasks, and parameters that are likely to change underfoot. Unfortunately, bugs and crashes also come along with the Beta release territory. We will do our best to stamp these out as soon as we find them, but sometimes known bugs will persist until we can find the right time to fix them (like in a task that we know we want to make a big change to next month). See the release notes for the current version for more details. In this cookbook, we will try to point out known pitfalls and workarounds in the Beta Alert boxes, or in BETA ALERT notes in the text.

Not only is the software in Beta Release, but this cookbook is also a living document. You can expect this document, as well as other on-line and in-line user support guides, to be updated regularly. Also, feel free to send us comments and suggestions on the contents of our documentation.

Please check the CASA Home page (http://casa.nrao.edu) regularly to look for updates to the release and to the documentation, and to check the list of known problems. You can find the contact information for feedback here also.

We also note here that we are also in the process of commissioning our User Support system for CASA. Thus, we can only support a limited number of official Beta Release Users at this time. See the CASA Home Page for more information on the policies and conditions on obtaining and getting support for this Beta Release.
CHAPTER 1. INTRODUCTION

1.1.1 What’s New in Beta Patch 4

This Cookbook is for CASA Beta Release Patch 4 (version Versions 2.4.0). This patch differs from previous versions of CASA in a number of ways:

- New interface changes:
  - The AIPSPATH environment variable is now the CASAPATH variable.
  - If you type help task without quotes around the task name, you will get two copies of the help with alot of extraneous stuff. This is a bug introduced in 2.4.0 and will be fixed in later releases.

- New data handling features:
  - A number of importvla improvements were made:
    1. In previous releases, importvla did not provide a valid DOPPLER subtable. This has been fixed in 2.4.0. release.
    2. The keepblanks parameter is defaulted to False, so tipping scans will not be included in the measurement set. Setting this to True will include the tipping scans.
    3. Data edited as having zero weight are now flagged, instead of simply being carried around with a weight of 0. This fixes an issue in the viewer where existing flags were ignored while performing additional flagging.
    4. VLA antennas are now sorted into numerical (name) order, and the station naming has been enhanced to include the VLA/EVLA distinction.
    5. Duplicate field names for different source positions in the archive (a rare occurrence) are resolved with an appended digit to permit selecting such fields uniquely in subsequent processing.
  - The task importuvfits has a new parameter antnamescheme (as in importvla) which when set to ’new’ and you are importing VLA data, then it will prepend either VA or EV to the antenna name (§ 2.2.1.1).
  - Data can be compressed in importasdm by setting compression = True (§ 2.2.3).
  - The concat task now has a timesort parameter to trigger time-based resorting of the output MS (§ 2.5).
  - A number of changes to listobs output, including reporting of rest frequency and velocity information, integration time, source identification, time frame (§ 2.3).
  - There is a prototype vishead task that allows the user to manipulate some common metadata items in a measurement set (e.g. to list, get, and put values) (§ 2.4).
  - A new task called rmtables has been created to cleanly remove tables. This helps if the user is trying to process data (e.g. an image) from scratch, and not continue from a previous session. It will not remove things that have open handles (§ 1.4.3.1).

- New plotting and flagging features:
  - A number of changes were made to flagdata (§ 3.5):
1. The task now has the feature where some parameters can take lists, so only one invocation of the task can apply any number of flagging specification.
2. The task now uses the standard selectdata parameters.
3. The correlation sub-parameter now takes more options, e.g. 'RR LL', 'RR,LL', etc.
4. The mode parameter now has a 'shadow' option.
   - The task plotants now has the capability to save a plot as a file (parameter figfile). §3.7.
   - There is a new prototype MS plotting application casaplotms. This is experimental and under active development, and is not yet integrated into casapy §3.8.

New synthesis calibration features:
- There are models for 3C147 at C and X band now available in setjy §4.3.4.
- In the calibration tasks, there is now a minblperant parameter, which enables the user to control the minimum number of baselines required for an antenna to be solved for §4.4.1.5.
- The task split can now go directly from a multi SPW measurement set to a time averaged one with the same set of SPWs, and/or split to a single SPW at the same time §4.7.1.
- The split task can now do frequency averaging then time averaging consecutively with no issues. §4.7.1.
- The split task datacolumn parameter now takes options 'data', 'corrected', 'model', 'all' §4.7.1.

New synthesis imaging features:
- A number of clean improvements were made:
  1. The mode parameter has a new sub-parameter interpolation to control how data is gridded onto the spectral cube axis in channel, velocity, and frequency modes. This has 3 possible values: 'nearest', 'linear', and 'cubic'. §5.2.5.5.
  2. There were a number of cosmetic and functional changes made to the interactive clean viewer panel §5.3.5.
  3. In clean if you are reducing data from a telescope whose beam is not found in the list of known arrays in CASA, the dish diameter (found in the antenna table) is used to scale an Airy disk pattern beam §5.2.13.
  4. Option stokes = 'IQU' is now available.
  5. The psfmode settings 'hogbom' does sequential cleaning while 'clark' and 'csclean' do joint convolution.
  6. For imagermode='mosaic' the minpb parameter now cuts the imaging off at the specified level in the unweighted primary-beam coverage, as reflected in the new output image <imagename>.flux.pbcoverage §5.3.7.

New image analysis features:
– All of the WCS projections for FITS images described in the FITS standard v3.0 are now supported by CASA. CASA will read and write standard-compliant FITS images. FITS image files that are not WCS compliant are accepted by applying a dummy linear coordinate along each axis.

– In FITS images, all brightness units complying with the FITS standard v3.0 are recognized. Non-recognized units are accepted and treated as “non-dimensional”. The unit maps in quanta and the FITS unit add-on were extended to cover the FITS standard v3.0.

– There is a new task called imsmooth that will smooth images in the spectral and XY planes. (§6.10).

– All of the image analysis tasks (imstat, imval, etc.) with the region parameter have been updated to take as input: region file name saved by the viewers region manager, region name stored with the image given by imagename, region in any image with the syntax image_filename:region_name.

• New viewer features:
  – The viewer Maximum Contour slider has been replaced with the Unit Contour slider, found under basic settings (§7.3.2).
  – The region manager on the viewer has changed, and you can now save regions with an image file and/or on disk (§7.3.3).

• New single-dish processing features:
  – The sdfit task now has the capability to plot the whole spectral region to see the entire spectral shape when the fitted result is verified (§A.2.1.7).
  – In the sdbaseline and sdcal tasks the parameter interactive has been renamed as verify (§A.2.1).
  – In the sdcal task interactive mask selection is enabled with blmode = 'interact' (§A.2.1.4).
  – It is now possible in sdplot to get statistics by selecting a region with mouse button on a plot displayed by the task. (§A.2.1.10).
  – There are a number of other changes, as this CASA module is under continuous development. See the Appendix A for the latest guide.

• New simulator features:
  – The simulator task is now called simdata (used to be almasimmos). This task has many new features (§B).

1.1.1.1 Previous changes in Patch3

CASA Beta Release Patch 3 (version 2.3.0) was released in December 2008. In January 2009, we released an update to Patch 3 as Version 2.3.1. This fixed and updated a small number of issues encountered in the original Patch 3 release version 2.3.0.
CHAPTER 1. INTRODUCTION

• New interface changes:
  – The versioning of CASA has changed such that the startup and casalog.version now report Version X.Y.Z where X=2 for the Beta Release, Y is the Patch number, and Z is the sub-patch release. For example, the December 2008 Patch 3.0 release is Version 2.3.0.

• New data handling features:
  – The importasdm task now has better handling of ALMA ATF data (§2.2.3).

• New plotting and flagging features:
  – The plotxy task now has the extendflag parameter and sub-parameters that allow the extension of interactive flagging to data cells beyond those plotted (§3.4.6).
  – The plotxy task now has the restfreq parameter and sub-parameters that allow the setting of a rest frequency or transition name as well as frame info (§3.4.7).

• New synthesis calibration features:
  – The bandtype='BPOLY' option now has the capability of getting solutions in different sets of spectral windows (§4.4.2.3).

• New synthesis imaging features:
  – NEW: widefield — a prototype task to make wide-field (e.g. low frequency) images using w-projection and/or faceting. Includes the ability to image multiple flanking fields set up using a box file (§5.4).
  – The clean task now handles multiple dish sizes for heterogeneous imaging (§5.3.15).
  – The clean task has been improved in its handling of mosaics (§5.3.14).

• New image analysis features:
  – NEW: imval — a task that will return the data values in an image at a given pixel or in a specified region (§6.8).
  – The imfit task has improved reporting of fit results (§6.4).
  – The task regrid has been renamed imregrid. This task will regrid an image onto a template image (§6.9).

• New viewer features:
  – The viewer now includes the ability to Save and Restore the GUI settings via a Data menu item (§7.2.2).
  – There is now improved control and appearance of Printing from the viewer (§7.5).

• New documentation features:
  – There is now an appendix on how to write and include your own CASA tasks, intended for the power-user (§H).
  – There is now an online CASA Task Reference Manual.
1.1.1.2 Previous changes introduced in Patch 2

These were changes made in July 2008 with Beta Release Patch 2.0–2.2:

- New interface changes:
  - Global parameters (variables) are not changed in task calls (§1.3.5.1).
  - Global parameters (variables) are not used if a task is called as a function with one or more arguments specified, e.g. task(arg1=val1,...). Non-specified parameters are defaulted to the task-specific default values (§1.3.2).
  - Return values from tasks are used instead of output variables (§1.3.3).

- New data handling features:
  - The concat task now takes multiple input MS and will combine into a possibly new output MS (§2.5).

- New synthesis calibration features:
  - The calibration tasks now include a combine which allows control of the scope of solutions (§4.4.1.5).
  - The behavior of the solint parameter has changed, with solint=0 now giving per-integration solutions instead of per-scan. This is used in conjunction with combine to control solution scope (§4.4.1.5).

- New synthesis imaging features:
  - The clean task now incorporates the features of old tasks invert and mosaic, with added capabilities (§5.3).

- New image analysis features:
  - Lattice Expression Language (LEL) in the image analysis tasks and tools is now fully 0-based, while previously it was partly 1-based. This is most noticeable in the immoments task with the planes parameter, and in using the INDEXIN LEL function in the ia tool methods (§6.1.3).
  - NEW: imfit — a task to do image-plane Gaussian fitting (§6.4).
  - The immath task now includes the options to make spectral index, linearly polarized intensity and angle images (§6.5).

- New viewer features:
  - The viewer now includes a Region Manager tool that can save the last box or polygon region to a file. In addition, the pixel coordinates under the cursor are displayed in the Position Tracking panel. (§7).

WARNING: Some of these changes will require scripts from Patch 1 or earlier to be changed. In some cases, you may not get an error but will get noticeably different behavior (e.g. from the solint changes in Calibration).
1.2 CASA Basics — Information for First-Time Users

This section assumes that CASA has been installed on your LINUX or OSX system. See Appendix C for instructions on how to obtain and install CASA.

1.2.1 Before Starting CASA

First, you will most likely be starting CASA running from a working directory that has your data in it, or at least where you want your output to go. It is easiest to start from there rather than changing directories inside casapy. **BETA ALERT:** There is at least one task (plotxy) that fails if the path to your working directory contains spaces in its name, e.g. `/users/smyers/MyTest/` is fine, but `/users/smyers/My Test/` is not! We will try to bulletproof the file-handling better.

If you have done a default installation under Linux using rpms, or on the Mac with the CASA application, then there should be a sh script called `casapy` in the `/usr/bin` area which is in your path. This shell will set up its environment and run the version of `casapy` that it points to. If this is how you set up the system, then you need to nothing further and can run `casapy`.

Depending on your setup, there may be other specially built versions available. For example at the NRAO AOC, the “stable build” can be started by running “casapy-test”, e.g.

```
/usr/bin/casapy-test
```

On some systems, particularly if you have multiple versions installed, to define environment variables and the `casapy` alias, you will need to run one of the `casainit` shell scripts. The location of the startup scripts for CASA will depend upon where you installed CASA on your system. For a default installation this will likely be in `/usr/lib/casapy/`. For example, at the NRAO AOC, the current release is executed as

```
/usr/bin/casapy
```

and uses the pathname to

```
/usr/lib/casapy/23.0.6654-001
```

Sometimes, you will have multiple non-default versions (for example, various development versions). For example at the NRAO AOC, the “stable build” is in `/home/casa`. Then, to use this version:

```
In bash:
> . /home/casa/casainit.sh
or for csh:
> source /home/casa/casainit.csh
```

depending on what shell you are running (Bourne or [t]csh).

**BETA ALERT:** If you want to run the `casabrowser` (see §3.6) outside of the `casapy` shell, then you will need to put the CASA root in your path using one of the above mechanisms.
1.2.1.1 Environment Variables

Before starting up casapy, you should set or reset any environment variables needed, as CASA will adopt these on startup. For example, the PAGER environment variable determines how help is displayed in the CASA terminal window (see §1.2.8.3). The choices are less, more, and cat.

In bash, pick one of

PAGER=less
PAGER=more
PAGER=cat

followed by

export PAGER

In csh or tcsh, pick one of

setenv PAGER less
setenv PAGER more
setenv PAGER cat

The actions of these are as if you were using the equivalent Unix shell command to view the help material. See §1.2.8.3 for more information on these choices. We recommend using the cat option for most users, as this works smoothly both interactively and in scripts.

**BETA ALERT:** There is currently no way within CASA to change these environment variables.

1.2.1.2 Where is CASA?

Note that the path to the CASA installation, which contains the scripts and data repository, will also depend upon the installation. With a default installation under Linux this will probably be in

/usr/lib/casapy/

while in a Mac OSX default install it will likely be an application (in the Applications folder), with the data repository in:

/opt/casa/

You can find the location after initialized by looking at the CASAPATH environment variable. You can find it within casapy by

```python
pathname=os.environ.get('CASAPATH').split()[0]
print pathname
```

**BETA ALERT:** Previous to release 2.4.0 this was called AIPSPATH.
1.2.2 Starting CASA

After having run the appropriate casainit script, CASA is started by typing `casapy` on the UNIX command line, e.g.

```
casapy
```

After startup information, you should get an IPython CASA <1> command prompt in the xterm window where you started CASA. CASA will take approximately 10 seconds to initialize at startup in a new working directory; subsequent startups are faster. CASA is active when you get a CASA <1> prompt in the command line interface. You will also see a `logger` GUI appear on your Desktop (usually near the upper left). *Note: Under MacOSX the logger will appear in a Console window.*

You also have the option of starting CASA with various `logger` options (see §1.4.2.1). For example, if you are running remotely in a terminal window without an X11 connection, or if you just do not want to see the logger GUI, and want the `logger` messages to come to your terminal, do

```
casapy --nologger --log2term
```

See §1.4.2 for information on the `logger` in general.

1.2.3 Ending CASA

You can exit CASA by typing `quit`. This will bring up the query

```
Do you really want to exit ([y]/n)?
```

to give you a chance in case you did not mean to exit. You can also quit using `%exit` or `CTRL-D`.

If you don’t want to see the question "Do you really want to exit [y]/n?", then just type `Exit` or `exit` and CASA will stop right then and there.

1.2.4 What happens if something goes wrong?

**BETA ALERT:** This is a Beta Release, and there are still ways to cause CASA to crash. Please check the CASA Home Page for Beta Release information including a list of known problems. If you think you have encountered an unknown problem, please consult the CASA HelpDesk (contact information on the CASA Home Page). See also the caveats to this Beta Release (§1.1 for pointers to our policy on User Support.

First, always check that your inputs are correct; use the
help <taskname>

(§ 1.2.8.2) or

help par.<parameter name>

(§ 1.2.8.4) to review the inputs/output.

1.2.5 Aborting CASA execution

If something has gone wrong and you want to stop what is executing, then typing CNTL-C (Control and C keys simultaneously) will usually cleanly abort the application. This will work if you are running a task synchronously. If this does not work on your system, or you are running a task asynchronously (§ 1.3.4) then try CNTL-Z to put the task or shell in the background, and then follow up with a kill -9 <PID> where you have found the relevant casapy process ID (PID) using ps (see § 1.2.6 below).

See § 1.3.2 for more information on running tasks.

If the problem causes CASA to crash, see the next sub-section.

1.2.6 What happens if CASA crashes?

Usually, restarting casapy is sufficient to get you going again after a crash takes you out of the Python interface. Note that there may be spawned subprocesses still running, such as the casaviewer or the logger. These can be dismissed manually in the usual manner. After a crash, there may also be hidden processes. You can find these by listing processes, e.g. in linux:

    ps -elf | grep casa

or on MacOSX (or other BSD Unix):

    ps -aux | grep casa

You can then kill these, for example using the Unix kill or killall commands. This may be necessary if you are running remotely using ssh, as you cannot logout until all your background processes are terminated. For example,

    killall ipcontroller

or

    killall Python

will terminate the most common post-crash zombies.
1.2.7 Python Basics for CASA

Within CASA, you use Python to interact with the system. This does not mean an extensive Python course is necessary - basic interaction with the system (assigning parameters, running tasks) is straightforward. At the same time, the full potential of Python is at the more experienced user’s disposal. Some further details about Python, IPython, and the interaction between Python and CASA can be found in Appendix D.

The following are some examples of helpful hints and tricks on making Python work for you in CASA.

1.2.7.1 Variables

Python variables are set using the `<parameter> = <value>` syntax. Python assigns the type dynamically as you set the value, and thus you can easily give it a non-sensical value, e.g.

```
vis = 'ngc5921.ms'
vis = 1
```

The CASA parameter system will check types when you run a task or tool, or more helpfully when you set inputs using `inp` (see below). CASA will check and protect the assignments of the global parameters in its namespace.

Note that Python variable names are case-sensitive:

```
CASA <109>: Foo = 'bar'
CASA <110>: foo = 'Bar'
CASA <111>: foo
  Out[111]: 'Bar'
CASA <112>: Foo
  Out[112]: 'bar'
```

so be careful.

Also note that mis-spelling a variable assignment will not be noticed (as long as it is a valid Python variable name) by the interface. For example, if you wish to set `correlation='RR'` but instead type `corellation='RR'` you will find `correlation` unset and a new `corellation` variable set. Command completion (see §1.2.8.1) should help you avoid this.

1.2.7.2 Lists and Ranges

Sometimes, you need to give a task a list of indices. If these are consecutive, you can use the Python `range` function to generate this list:

```
CASA <1>: iflist=range(4,8)
CASA <2>: print iflist
```
[4, 5, 6, 7]
CASA <3>: iflist=range(4)
CASA <4>: print iflist
[0, 1, 2, 3]

See Appendix D.3 for more information.

1.2.7.3 Indexes

As in C, Python indices are 0-based. For example, the first element in a list `antlist` would be `antlist[0]`:

CASA <113>: antlist=range(5)
CASA <114>: antlist
  Out[114]: [0, 1, 2, 3, 4]
CASA <115>: antlist[0]
  Out[115]: 0
  Out[116]: 4

CASA also uses 0-based indexing internally for elements in the Measurement Set (MS – the basic construct that contains visibility and/or single dish data; see Chapter 2). Thus, we will often talk about Field or Antenna “ID”s which will be start at 0. For example, the first field in an MS would have FIELD_ID==0 in the MSselect syntax, and can be addressed as be indexed as `field='0'` in most tasks, as well as by name `field='0137+331'` (assuming thats the name of the first field).

You will see these indices in the MS summary from the task `listobs`.

1.2.7.4 Indentation

Python pays attention to the indentation of lines, as it uses indentation to determine the level of nesting in loops. Be careful when cutting and pasting: if you get the wrong indentation, then unpredictable things can happen (usually it just gives an error).

See Appendix D.2 for more information.

1.2.7.5 System shell access

If you want to access system commands from a script, use the `os.system` command (Appendix D.6.1).

In interactive mode, any input line beginning with a ‘!’ character is passed verbatim (minus the ‘!’, of course) to the underlying operating system. Also, several common commands (`ls`, `pwd`, `less`) may be executed with or without the ‘!’, although the `cp` command must use ‘!’ and `cd` must be executed without the ‘!’). For example:

CASA <5>: !rm -r mydata.ms
Note that if you want to access a Unix environment variable, you will need to prefix with a double $$ instead of a single $ — for example, to print the value of the $$PAGER$$ variable, you would use

```
CASA <6>: !echo $$PAGER
```

See Appendix D.6 for more information.

### 1.2.7.6 Executing Python scripts

You can execute Python scripts (ASCII text files containing Python or casapy commands) using the `execfile` command. For example, to execute the script contained in the file `myscript.py` (in the current directory), you would type

```
CASA <7>: execfile('myscript.py')
```

or

```
CASA <8>: execfile 'myscript.py'
```

which will invoke the IPython auto-parenthesis feature.

**NOTE:** in some cases, you can use the IPython `run` command instead, e.g.

```
CASA <9>: run myscript.py
```

In this case, you do not need the quotes around the filename. This is most useful for re-initializing the task parameters, e.g.

```
CASA <10>: run clean.last
```

(see § 1.3.5.7).

See Appendix D.11 for more information.

### 1.2.8 Getting Help in CASA

#### 1.2.8.1 TAB key

At any time, hitting the `<TAB>` key will complete any available commands or variable names and show you a list of the possible completions if there’s no unambiguous result. It will also complete filenames in the current directory if no CASA or Python names match.

For example, it can be used to list the available functionality using minimum match; once you have typed enough characters to make the command unique, `<TAB>` will complete it.
1.2.8.2 help <taskname>

Basic information on an application, including the parameters used and their defaults, can be obtained by typing `pdoc task`, `help 'task'` or `task?`. The `pdoc task` currently gives the cleanest documentation format with the smallest amount of object-oriented (programmer) output. This inline help provides a one line description of the task and then lists all parameters, a brief description of the parameter, the parameter default, an example setting the parameter and any options if there are limited allowed values for the parameter.

For example:

CASA <10>: pdoc importvla

Class Docstring:

Import VLA archive file(s) to a measurement set

Imports an arbitrary number of VLA archive-format data sets into a casa measurement set. If more than one band is present, they will be put in the same measurement set but in a separate spectral window. The task will handle old style and new style VLA (after July 2007) archive data and apply the tsys to the data and to the weights.

Keyword arguments:

archivefiles -- Name of input VLA archive file(s)
  default: none. Must be supplied
  example: archivefiles = 'AP314_A959519.xp1'
  example: archivefiles = ['AP314_A950519.xp1', 'AP314_A950519.xp2']

vis -- Name of output visibility file
  default: none. Must be supplied.
  example: vis='NGC7538.ms'
  Will not over-write existing ms of same name.
  A backup flag-file version 'Original' will be made in vis.flagversions. See help flagmanager

bandname -- VLA Frequency band
  default: => '' = all bands
  example: bandname='K'
  Options: '4'=48-96 MHz,'P'=298-345 MHz,'L'=1.15-1.75 GHz,'C'=4.2-5.1 GHz,'X'=6.8-9.6 GHz,'U'=13.5-16.3 GHz,'K'=20.8-25.8 GHz,'Q'=38-51 GHz

frequencytol -- Tolerance in frequency shift in making spectral windows
  default: => 150000 (Hz). For Doppler shifted data, <10000 Hz may
may produce too many unnecessary spectral windows.
example: frequencytol = 1500000.0 (units = Hz)

project -- Project name to import from archive files:
default: '' => all projects in file
example: project='AL519'
project = 'al519' or AL519 will work. Do not include
leading zeros; project = 'AL0519' will not work.

starttime -- Time after which data will be considered for importing
default: '' => all: Date must be included.
syntax: starttime = '2003/1/31/05:05:23'

stoptime -- Time before which data will be considered for importing
default: '' => all: Date must be included.
syntax: stoptime = '2003/1/31/08:05:23'

applytsys -- Apply data scaling and weight scaling by nominal
sensitivity (~Tsys)
default: True. Strongly recommended

autocorr -- import autocorrelations to ms
default: => False (no autocorrelations)

antnamescheme -- 'old' or 'new' antenna names.
default => 'new' gives antenna names
'VA04' or 'EA13 for VLA telescope 04 and 13 (EVLA)
'old' gives names '04' or '13'

async -- Run asynchronously
default = False; do not run asynchronously

Constructor Docstring:
None

**BETA ALERT:** If you type `help task` without quotes around the `task` name, you will get two copies of the help with a lot of extraneous stuff. This is a bug introduced in 2.4.0 and will be fixed in later releases.

You can also get the short help for a CASA tool method by typing 'help tool.method'.

```casa
CASA <46>: help ia.subimage
--------------> help(ia.subimage)
Help on built-in function subimage:

subimage(...)  
Create a (sub)image from a region of the image`:
  outfile
  region
  mask
  dropdeg = false
  overwrite = false
  list = true

```

For a full list of keywords associated with the various tools, see the **CASA User Reference Manual.** **BETA ALERT:** The User Reference Manual currently covers only tools, not tasks.
1.2.8.3 help and PAGER

Your PAGER environment variable (§1.2.1) determines how help is displayed in the terminal window where you start CASA. If you set your bash environment variable PAGER=less (setenv PAGER less in csh) then typing help <taskname> will show you the help but the text will vanish and return you to the command line when you are done viewing it. Setting PAGER=more (setenv PAGER more) will scroll the help onto your command window and then return you to your prompt (but leaving it on display). Setting PAGER=cat (setenv PAGER cat) will give you the more equivalent without some extra formatting baggage and is the recommended choice.

If you have set PAGER=more or PAGER=less, the help display will be fine, but the display of ‘taskname?’ will often have confusing formatting content at the beginning (lots of ESC surrounding the text). This can be remedied by exiting casapy and doing an ‘unset PAGER’ (unsetenv PAGER in [t]csh) at the Unix command line.

You can see the current value of the PAGER environment variable with CASA by typing:

```bash
!echo $$PAGER
```

(note the double $$). This will show what command paging is pointed to.

1.2.8.4 help par.<parameter>

Typing help par.<parameter> provides a brief description of a given parameter <parameter>.

```bash
CASA <46>: help par.robust
Help on function robust in module parameter_dictionary:

    robust()
    Brigg’s robustness parameter.

    Options: -2.0 (close to uniform) to 2.0 (close to natural)
```

1.2.8.5 Python help

Typing help at the casapy prompt with no arguments will bring up the native Python help facility, and give you the help> prompt for further information; hitting <RETURN> at the help prompt returns you to the CASA prompt.

```bash
CASA <2>: help
--------> help()

Welcome to Python 2.5! This is the online help utility.

If this is your first time using Python, you should definitely check out the tutorial on the Internet at http://www.python.org/doc/tut/.
```
Enter the name of any module, keyword, or topic to get help on writing Python programs and using Python modules. To quit this help utility and return to the interpreter, just type "quit".

To get a list of available modules, keywords, or topics, type "modules", "keywords", or "topics". Each module also comes with a one-line summary of what it does; to list the modules whose summaries contain a given word such as "spam", type "modules spam".

```
help> keywords
```

Here is a list of the Python keywords. Enter any keyword to get more help.

```
and  else  import  raise
assert except in return
break exec is try
class finally lambda while
continue for not yield
def from or
del global pass
elif if print
help>

# hit <RETURN> to return to CASA prompt

You are now leaving help and returning to the Python interpreter.
If you want to ask for help on a particular object directly from the interpreter, you can type "help(object)". Executing "help('string')" has the same effect as typing a particular string at the help> prompt.

Further help in working within the Python shell is given in Appendix D.

### 1.3 Tasks and Tools in CASA

Originally, CASA consisted of a collection of tools, combined in the so-called toolkit. Since the majority of prospective users is far more familiar with the concept of tasks, an effort is underway to replace most - if not all - toolkit functionality by tasks.

While running CASA, you will have access to and be interacting with tasks, either indirectly by providing parameters to a task, or directly by running a task. Each task has a well defined purpose, and a number of associated parameters, the values of which are to be supplied by the user. Technically speaking, tasks are built on top of tools - when you are running a task, you are running tools in the toolkit, though this should be transparent.

As more tasks are being written, and the functionality of each task is enhanced, there will be less
and less reason to run tools in the toolkit. We are working toward a system in which direct access to the underlying toolkit is unnecessary for all standard data processing.

1.3.1 What Tasks are Available?

As mentioned in the introduction, tasks in CASA are Python interfaces to the more basic toolkit. Tasks are executed to perform a single job, such as loading, plotting, flagging, calibrating, and imaging the data.

Basic information on tasks, including the parameters used and their defaults, can be obtained by typing `help <taskname>` or `<taskname>?` at the CASA prompt, where `<taskname>` is the name of a given task. As described above in §1.2.8.2, `help <taskname>` provides a description of the task and then lists all parameters, a brief description of the parameter, the parameter default, an example setting the parameter and any options if there are limited allowed values for the parameter.

To see what tasks are available in CASA, use `tasklist`, e.g.

```
CASA <4>: tasklist()
Available tasks:

Import/Export Information Data Editing Display/Plot
------------ ----------- ------------ -----------
importvla listcal flagautocorr clearplot
(importasdm) listhistory flagdata plotants
importfits listobs flagmanager plotcal
importuvfits listvis plotxy plotxy
exportfits imhead viewer
exportuvfits imstat vishead

Calibration Imaging Modelling Utility
------------ ------- --------- -------
accum clean setjy help
applycal deconvolve uvcinfo sub help par.parameter
bandpass feather uvmodelfit taskhelp
(hlcal) ft tasklist
gaincal invert browsetable
fluxscale makemask clearplot
clearcal mosaic clearstat
listcal mosaic
smoothcal stashgrid
polcal
hanningsmooth

Image Analysis Simulation Single Dish
------------ --------- -----------
imcontsub simdata sdaverage
```
CHAPTER 1. INTRODUCTION

imhead  sdbaseline
immath  sdcal
immoments  sdcoadd
imregrid  sdfit
imstat  sdflag
imval  sdlst
(specfit)  sdpot
sdsave
sdscale
sdsmooth
sdstat

The tasks with name in parentheses are experimental.

Typing taskhelp provides a one line description of all available tasks.

CASA <5>: taskhelp()
Available tasks:

accum  Accumulate incremental calibration solutions into a calibration table
almasimmos  ALMA mosaic simulation task (prototype):
applycal  Apply calibrations solutions(s) to data
bandpass  Calculates a bandpass calibration solution
bical  Calculate a baseline-based calibration solution (gain or bandpass)
browsetable  Browse a table (MS, calibration table, image)
clean  Deconvolve an image with selected algorithm
clearcal  Re-initializes the calibration for a visibility data set
clearplot  Clear the matplotlib plotter and all layers
clearstat  Clear all read/write locks
concat  Concatenate two visibility data sets.
deconvolve  Image based deconvolver
exportfits  Convert a CASA image to a FITS file
exportuvfits  Convert a CASA visibility data set to a UVFITS file:
feather  Feathering: Combine two images using the Fourier Addition
find  Find string in tasks, task names, parameter names:
flagautocorr  Flag autocorrelations
flagdata  All purpose flagging task based on selections
flagmanager  Enable list, save, restore and delete flag version files.
fluxscale  Bootstrap the flux density scale from standard calibrators
fringecal  Calculate a baseline-based fringe-fitting solution (phase, delay, delay-rate); Note: current implementation is limited to delays and delay-rates in the central ambiguity
ft  Insert a source model into the MODEL_DATA column of a visibility set:
gaincal  Determine temporal gains from calibrator observations
hanningsmooth  Hanning smooth frequency channel data to remove Gibbs ringing
imcontsub  Subtracts specified continuum channels from a spectral line data set
imfit  Fit One Elliptical Gaussian Component on an image region(s)
imhead  List, get and put image header parameters
immath  Perform math operations on images
immoments  Compute moments from an image
importasdm  Convert an ALMA Science Data Model observation into a CASA visibility file
importfits  Convert an image FITS file into a CASA image
importuvfits  Convert a UVFITS file to a CASA visibility data set
importvla : Import VLA archive file(s) to a measurement set
imregrid : regrid an image onto a template image
imstat : Displays statistical information from an image or image region
imval : Get the data value(s) and/or mask value in an image.
imvert : Calculate the dirty image and dirty beam from a visibility set
listcal : List calibrated antenna gain solutions
listhistory : List the processing history of a dataset:
listobs : List data set summary in the logger
listvis : List measurement set visibilities.
makemask : Derive a mask image from a cleanbox blc, trc regions
mosaic : Create a multi-field deconvolved image with selected algorithm
newclean : Deconvolve an image with selected algorithm
newflagdata : Flag/Clip data based on selections
oldclean : Deconvolve an image with selected algorithm
plotants : Plot the antenna distribution in the local reference frame:
plotcal : An all-purpose plotter for calibration results
plotxy : An X-Y plotter/interactive flagger for visibility data.
polcal : Determine instrumental polarization calibrations
sdaverage : ASAP SD task: do data selection, calibration, and averaging
sdbaseline : ASAP SD task: fit/remove a spectral baseline
sdclean : ASAP SD task: do sdaverage, sdsmooth, and sdbaseline in one task
sdcload : ASAP SD task: coadd multiple scantables into one
sdfit : ASAP SD task: fit a spectral line
sdflag : ASAP SD spectral flagging task
sdlist : ASAP SD task: list summary of single dish data
sdplot : ASAP SD plotting task
sdsave : ASAP SD task: save the sd spectra in various format
sdscale : ASAP SD task: scale the sd spectra
sdsmooth : ASAP SD task: do smoothing of spectra
sdstat : ASAP SD task: list statistics of spectral region
sdtpimaging : SD task: do a simple calibration and imaging for total power data
setjy :
smoothcal : Smooth calibration solution(s) derived from one or more sources:
(specfit) : Fit 1-dimentional profile(s) or polynomial(s) to an image or image region
split :
uvcontsub : Continuum fitting and subtraction in the uv plane
uvmodelfit : Fit a single component source model to the uv data
uvsub : Subtract/add model from/to the corrected visibility data.
viewer : View an image or visibility data set:
widefield : Wide-field imaging and deconvolution with selected algorithm

Typing startup will provide the startup page displayed when entering CASA. For example,

CASA <6>: startup()

---------------------------------------------
Available tasks:

    accum  flagdata  invert  sdbase
    applycal  flagmanager  listcal  sdlist
    bandpass  fluxscale  listhistory  sdplot
CHAPTER 1. INTRODUCTION

browsetable ft listobs sdsave
clean gaincal listvis sdscale
clearcal hanningsmooth makemask sdsMOOTH
clearplot imcontsub mosaic sdstat
clearstat imhead plotants setjy
concat immoments plotcal smoothcal
deconvolve importfits plotxy specfit
exportfits importuvfits sdaVERAGE split
exportuvfits importvls sdbaseline tget
feather imregrid sdcal uvcontsub
filecatalog imstat sdciadd uvmodelfit
find imval sdfit viewer

Additional tasks available for ALMA commissioning use
(still alpha code as of release):
simdata blcal fringeCAL importasdm

Available tools:
  cb (calibrater) cp (cal plot) fg (flagger)
  ia (image analysis) im (imager) me (measures)
  mp (MS plot) ms (MS) qa (quanta)
  sm (simulation) tb (table) tp (table plot)
  vp (voltage patterns)

  pl (pylab functions)
  sd (ASAP functions - run asap_init() to import into CASA)
  casaloggEr - Call up the casaloggEr (if it goes away)

Help :
  help taskname - Full help for task
  help par.parametername - Full help for parameter name
  find string - Find occurrences of string in doc
  tasklist - Task list organized by category
  taskhelp - One line summary of available tasks
  toolhelp - One line summary of available tools
  startup - The start up screen

1.3.2 Running Tasks and Tools

Tools are functions linked to the Python interface which must be called by name with arguments. Tasks have higher-level capabilities than tools. Tasks require input pa-
parameters which maybe be specified when you call the task as a function, or be set as parameters in the interface. A task, like a tool, is a function under Python and may be written in Python, C, or C++ (the CASA toolkit is made up of C++ functions).

There are two distinct ways to run tasks. You can either set the global CASA parameters relevant to the task and tell the task to “go”, or you can call the task as a function with one or more arguments specified. These two invocation methods differ in whether the global parameter values are used or not.

For example,

```python
default('plotxy')
vis='ngc5921.ms'
xaxis='channel'
yaxis='amp'
datacolumn='data'
go
```

will execute `plotxy` with the set values for the parameters (see §1.3.5). Instead of using `go` command (§1.3.5.3) to invoke the task, you can also call the task with no arguments, e.g.

```python
default('plotxy')
vis='ngc5921.ms'
xaxis='channel'
yaxis='amp'
datacolumn='data'
plotxy()
```

which will also use the global parameter values.

Second, one may call tasks and tools by name with parameters set on the same line. Parameters may be set either as explicit `<parameter>=<value>` arguments, or as a series of comma delimited `<value>`s in the correct order for that task or tool. Note that missing parameters will use the default values for that task. For example, the following are equivalent:

```python
# Specify parameter names for each keyword input:
plotxy(vis='ngc5921.ms',xaxis='channel',yaxis='amp',datacolumn='data')
# when specifying the parameter name, order doesn't matter, e.g.:
plotxy(xaxis='channel',vis='ngc5921.ms',datacolumn='data',yaxis='amp')
# use parameter order for invoking tasks
plotxy('ngc5921.ms','channel','amp','data')
```

This non-use of globals when calling as a function is so that robust scripts can be written. One need only cut-and-paste the calls and need not worry about the state of the global variables or what has been run previously. It is also more like the standard behavior of function calls in Python and other languages.

Tools can only be called in this second manner by name, with arguments (§1.3.6). Tools never use the global parameters and the related mechanisms of `inp` and `go`.  

**CHAPTER 1. INTRODUCTION**
1.3.2.1 Aborting Synchronous Tasks

If you are running CASA tasks synchronously, then you can usually use CNTL-C to abort execution of the task. If this does not work, try CNTL-Z followed by a kill. See §1.2.5 for more on these methods to abort CASA execution.

You may have to quit and restart CASA after an abort, as the internal state can get mixed up.

1.3.3 Getting Return Values

Some tasks and tools return a record (usually a Python dictionary) to the interface. For example, the `imstat` task (§6.7) returns a dictionary with the image statistics in it. To catch these return values into a Python variable, you MUST assign that variable to the task call, e.g.

```python
xstat = imstat('ngc5921.clean.image')
```

or

```python
default('imstat')
    imagename = 'ngc5921.clean.image'
    xstat = imstat()
```

Note that tools that return values work in the same way (§1.3.6).

You can print or use the return value in Python for controlling scripts. For example,

```plaintext
CASA <1>: xstat = imstat('ngc5921.clean.image')
CASA <2>: xstat
Out[2]:
{'blc': array([0, 0, 0, 0]),
 'blcf': '15:24:08.404, +04.31.59.181, I, 1.41281e+09Hz',
 'flux': array([ 4.15292207]),
 'max': array([ 0.05240594]),
 'maxpos': array([134, 134, 0, 38]),
 'maxposf': '15:21:53.976, +05.05.29.998, I, 1.41374e+09Hz',
 'mean': array([ 1.62978083e-05]),
 'medabsdevmed': array([ 0.00127287]),
 'median': array([-1.10467618e-05]),
 'min': array([-0.0105249]),
 'minpos': array([160, 1, 0, 30]),
 'minposf': '15:21:27.899, +04.32.14.923, I, 1.41354e+09Hz',
 'npts': array([ 3014656.]),
 'quartile': array([ 0.00254587]),
 'rms': array([ 0.00201818]),
 'sigma': array([ 0.00201811]),
 'sum': array([ 49.1322855]),
 'sumsq': array([ 12.27880404]),
 'trc': array([255, 255, 0, 45]),
```
'trcf': '15:19:52.390, +05.35.44.246, I, 1.41391e+09Hz'}
CASA <3>: myrms = xstat['rms'][0]
CASA <4>: print 10.0*myrms
0.0201817648485

If you do not catch the return variable, it will be lost

imstat('ngc5921.clean.image')

or

default('imstat')
imagename = 'ngc5921.clean.image'
imstat()

and spewed to terminal. Note that go will trap and lose the return value, e.g.

default('imstat')
imagename = 'ngc5921.clean.image'
go

will not dump the return to the terminal either.

NOTE: You cannot currently catch a return value from a task run asynchronously (§1.3.4).

**BETA ALERT:** Before Patch 2, the return values for tasks like `imstat` and `imhead` were put into the global variables (`xstat` and `hdvalue` respectively). This is no longer the case.

### 1.3.4 Running Tasks Asynchronously

By default, most tasks run synchronously in the foreground. Many tasks, particularly those that can take a long time to execute, have the `async` parameter. This allows the user to send the task to the background for execution.

**BETA ALERT:** A few tasks, such as the `exportuvfits` and `exportfits` tasks, have `async=True` by default. This is a workaround for a known problem where they can trample on other tasks and tools if they use the default global tools underneath.

#### 1.3.4.1 Monitoring Asynchronous Tasks

**BETA ALERT:** Currently, this is only available with the `tm` tool. We are working on a `taskmanager` task.
There is a “taskmanager” tool \texttt{tm} that allows the user to retrieve the status of, and to abort the execution of, tasks running with \texttt{async=True} in the background. There are two methods of interest for the user, \texttt{tm.retrieve} and \texttt{tm.abort}.

If you run a task with \texttt{async=True} then several things will happen. First of all, the task returns a “handle” that is a number used to identify the process. This is printed to the screen, e.g.

\begin{Verbatim}
CASA <5>: inp()
# mosaic :: Calculate a multi-field deconvolved image with selected clean algorithm:
... async = True # if True run in the background, prompt is freed
CASA <6>: mosaic()
Connecting to controller: ('127.0.0.1', 60775)
Out[6]: 0
\end{Verbatim}

where the output value 0 is the handle id.

You can also catch the return value in a variable, e.g.

\begin{Verbatim}
CASA <7>: handle = mosaic()
...
CASA <8>: print handle
1
\end{Verbatim}

You should also see the usual messages from the task in the \texttt{logger}, with some extra lines of information

\begin{verbatim}
###############################################
### Begin Task: mosaic ###
Tue Oct 2 17:58:16 2007 NORMAL ::mosaic:
""
"Use: "
tm.abort(return_value) # to abort the asynchronous task
tm.retrieve(return_value) # to retrieve the status
"
... usual messages here ... 

### End Task: mosaic ###
###############################################
""
\end{verbatim}

for the example above.

To show the current state of an asynchronous task, use the \texttt{tm.retrieve} method using the handle id as the argument. For example,
CHAPTER 1. INTRODUCTION

CASA <9>: tm.retrieve(handle)
    Out[9]: {'result': None, 'state': 'pending'}

or

CASA <10>: tm.retrieve(1)
    Out[10]: {'result': None, 'state': 'pending'}

which means it's still running. You should be seeing output in the logger also while the task is running.

When a task is finished, you will see:

CASA <11>: tm.retrieve(1)
    Out[11]: {'result': None, 'state': 'done'}

which indicates completion.

1.3.4.2 Aborting Asynchronous Tasks

To abort a task while it is running in the background, use the tm.abort method, again with the task handle id as the argument. For example,

CASA <12>: handle = mosaic()
    ...
CASA <13>: tm.abort(handle)

will abort the task if it is running.

If this does not work, try CNTL-Z followed by a kill -9 <PID> for the appropriate process ID. See §1.2.5 for more on these methods to abort CASA execution.

1.3.5 Setting Parameters and Invoking Tasks

One can set parameters for tasks (but currently not for tools) by performing the assignment within the CASA shell and then inspecting them using the inp command:

CASA <30>: default(bandpass)
CASA <31>: vis = 'ngc5921.demo.ms'
CASA <32>: caltable = 'ngc5921.demo.bcal'
CASA <33>: field = '0'
CASA <34>: refant = '15'
CASA <35>: inp('bandpass')
    # bandpass :: Calculates a bandpass calibration solution
    vis = 'ngc5921.demo.ms'  # Name of input visibility file

Inside the Toolkit:
In the current version of CASA, you cannot use the task parameter setting features, such as the inp, default, or go commands, for the tools.
CHAPTER 1. INTRODUCTION

```python
caltab = 'ngc5921.demo.bcal' # Name of output gain calibration table
field = '0' # Select field using field id(s) or field name(s)
spw = '' # Select spectral window/channels
selectdata = False # Other data selection parameters
solint = 'inf' # Solution interval
combine = 'scan' # Data axes which to combine for solve (scan, spw, field)
refant = '15' # Reference antenna name
minblperant = 4 # Minimum baselines _per antenna_ required for solve
solnorm = False # Normalize average solution amplitudes to 1.0 (G, T only)
bandtype = 'B' # Type of bandpass solution (B or BPOLY)
fillgaps = 0 # Fill flagged solution channels by interpolation
append = False # Append solutions to the (existing) table
gaintable = '' # Gain calibration table(s) to apply on the fly
gainfield = '' # Select a subset of calibrators from gaintable(s)
interp = '' # Interpolation mode (in time) to use for each gaintable
spwmap = [] # Spectral windows combinations to form for gaintables(s)
gaincurve = False # Apply internal VLA antenna gain curve correction
opacity = 0.0 # Opacity correction to apply (nepers)
parang = False # Apply parallactic angle correction
async = False #
```

See §1.3.5.4 below for more details on the use of the `inputs` command.

All task parameters have **global** scope within CASA: the parameter values are common to all tasks and also at the CASA command line. This allows the convenience of not changing parameters that are shared between tasks but does require care when chaining together sequences of task invocations (to ensure proper values are provided).

If you want to reset the input keywords for a single task, use the `default` command (§1.3.5.2). For example, to set the defaults for the `bandpass` task, type:

```
CASA <30>: default('bandpass')
```

as we did above.

To inspect a single parameter value just type it at the command line. Continuing the above example:

```
CASA <36>: combine
Out[14]: 'scan'
```

CASA parameters are just Python variables.

Parameters for a given task can be saved by using the `saveinputs` command (see §1.3.5.5) and restored using the `execfile '<filename>'` command. Note that if the task is successfully executed, then a `<taskname>.last` file is created in the working directory containing the parameter values (see §1.3.5.7).

We now describe the individual CASA task parameter interface commands and features in more detail.
1.3.5.1 The scope of parameters in CASA

All task parameters have global scope within CASA: the parameter values are common to all tasks and also at the CASA command line. This allows the convenience of not changing parameters that are shared between tasks but does require care when chaining together sequences of task invocations (to ensure proper values are provided). Tasks DO NOT change the values of the global parameters, nor does the invocation of tasks using the functional call with arguments change the globals.

This does mean that unless you do an explicit default of the task (§ 1.3.5.2), previously set values may be unexpectedly used if you do not inspect the inp carefully. For example, good practice is:

```python
default('imhead')
imagename = 'ngc5921.demo.cleaning.image'
mode = 'list'
imhead()
```

If you supply the task call with arguments, then these will be used for the values of those parameters (see above). However, if some but not all arguments are supplied, then those parameters not given as arguments will default and NOT use the current global values. Thus,

```python
imhead('ngc5921.demo.cleaning.image', mode='list')
```

will reproduce the above.

1.3.5.2 The default Command

Each task has a special set of default parameters defined for its parameters. You can use the default command to reset the parameters for a specified task (or the current task as defined by the taskname variable) to their default.

**Important Note:** The default command resets the values of the task parameters to a set of “defaults” as specified in the task code. Some defaults are blank strings ’’ or empty lists [], others are specific numerical values, strings, or lists. It is important to understand that just setting a string parameter to an empty string ’’ is not setting it to its default! Some parameters do not have a blank as an allowed value. See the help for a particular task to find out its default. If ’’ is the default or an allowed value, it will say so explicitly.

For example, suppose we have been running CASA on a particular dataset, e.g.
CHAPTER 1. INTRODUCTION

CASA <40>: inp clean
------------> inp('clean')
# clean :: Deconvolve an image with selected algorithm
vis = 'ngc5921.demo.src.split.ms.contsub' # name of input visibility file
imagename = 'ngc5921.demo.cleanimg' # Pre-name of output images
field = '0' # Field Name
spw = '' # Spectral windows:channels: '' is all
selectdata = False # Other data selection parameters
mode = 'channel' # Type of selection (mfs, channel, velocity, frequency)
   nchan = 46 # Number of channels (planes) in output image
   start = 5 # first input channel to use
   width = 1 # Number of input channels to average
   interpolation = 'nearest' # Spectral interpolation (nearest, linear, cubic)
niter = 6000 # Maximum number of iterations
...

and now we wish to switch to a different one. We can reset the parameter values using default:

CASA <41>: default
------------> default()

CASA <42>: inp
------------> inp()
# clean :: Deconvolve an image with selected algorithm
vis = '' # name of input visibility file
imagename = '' # Pre-name of output images
field = '' # Field Name
spw = '' # Spectral windows:channels: '' is all
selectdata = False # Other data selection parameters
mode = 'mfs' # Type of selection (mfs, channel, velocity, frequency)
niter = 500 # Maximum number of iterations
...

It is good practice to use default before running a task if you are unsure what state the CASA global variables are in.

BETA ALERT: You currently can only reset ALL of the parameters for a given task to their defaults. In an upcoming update we will allow the default command to take a second argument with a specific parameter to default its value.

1.3.5.3 The go Command

You can execute a task using the go command, either explicitly

CASA <44>: go listobs
------------> go(listobs)
Executing: listobs()
...
or implicitly if `taskname` is defined (e.g. by previous use of `default` or `inp`)

CASA <45>: taskname = 'clean'
CASA <46>: go
----------> go()
Executing: clean()
...

You can also execute a task simply by typing the `taskname`.

CASA <46>: clean
----------> clean()
Executing: clean()
...

The `go` command can also be used to launch a different task without changing the current `taskname`, without disrupting the `inp` process on the current task you are working on. For example

```
default 'gaincal' # set current task to gaincal and default
vis = 'n5921.ms' # set the working ms
... # set some more parameters
go listobs # launch listobs w/o chaning current task
inp # see the inputs for gaincal (not listobs!)
```

**BETA ALERT:** Doing `go listobs(vis='foo.ms')` will currently change the `taskname`, and will change `vis`, which might not be what is desired.

### 1.3.5.4 The `inp` Command

You can set the values for the parameters for tasks (but currently not for tools) by performing the assignment within the CASA shell and then inspecting them using the `inp` command. This command can be invoked in any of three ways: via function call `inp('<taskname>')` or `inp(<taskname>)`, without parentheses `inp '<taskname>'` or `inp <taskname>`, or using the current `taskname` variable setting with `inp`. For example,

```
CASA <1>: inp('clean')
...
CASA <2>: inp 'clean'
----------> inp('clean')
...
CASA <3>: inp(clean)
...
CASA <4>: inp clean
----------> inp(clean)
...
CASA <5>: taskname = 'clean'
CASA <6>: inp
----------> inp()
```
all do the same thing.

When you invoke the task inputs via inp, you see a list of the parameters, their current values, and a short description of what that parameters does. For example, starting from the default values,

CASA <18>: inp('clean')
# clean :: Deconvolve an image with selected algorithm
vis = '' # name of input visibility file
imagename = '' # Pre-name of output images
field = '' # Field Name
spw = '' # Spectral windows:channels: '' is all
selectdata = False # Other data selection parameters
mode = 'mfs' # Type of selection (mfs, channel, velocity, frequency)
niter = 500 # Maximum number of iterations
gain = 0.1 # Loop gain for cleaning
threshold = '0.0mJy' # Flux level to stop cleaning. Must include units
psfmode = 'clark' # method of PSF calculation to use during minor cycles
Imagermode = '' # Use casclean or mosaic. If '', use psfmode
multiscale = [] # multi-scale deconvolution scales (pixels)
interactive = False # use interactive clean (with GUI viewer)
mask = [] # cleanbox(es), mask image(s), and/or region(s)
imsize = [256, 256] # x and y image size in pixels
cell = ['1.0arcsec', '1.0arcsec'] # x and y cell size. default unit arcsec
phasecenter = '' # Image phase center: position or field index
restfreq = '' # rest frequency to assign to image (see help)
stakes = 'I' # Stokes params to image (eg I,IV, QU,IQUV)
weighting = 'natural' # Weighting of uv (natural, uniform, briggs, ...)
Uvtaper = False # Apply additional uv tapering of visibilities.
modelimage = '' # Name of model image(s) to initialize cleaning
restoringbeam = [''] # Output Gaussian restoring beam for CLEAN image
pbcor = False # Output primary beam-corrected image
minpb = 0.1 # Minimum PB level to use
async = False # If true the taskname must be started using clean(...)

Figure 1.1 shows how this will look to you on your terminal. Note that some parameters are in boldface with a gray background. This means that some values for this parameter will cause it to expand, revealing new sub-parameters to be set.

CASA uses color and font to indicate different properties of parameters and their values:

```
Parameter and Values in CASA inp
```
### Table 1.1: Parameters and Their Meanings

</table>

Figure 1.1: Screen shot of the default CASA inputs for task `clean`.

Figure 1.2 shows what happens when you set some of the `clean` parameters to non-default values. Some have opened up sub-parameters, which can now be seen and set. Figure 1.3 shows what happens when you set a parameter, in this case `vis` and `mode`, to an invalid value. Its value now appears in red. Reasons for invalidation include incorrect type, an invalid menu choice, or a filename that does not exist. For example, since `vis` expects a filename, it will be invalidated (red) if it is set to a non-string value, or a string that is not the name of a file that can be found. The `mode='happy'` is invalid because its not a supported choice (`'mfs'`, `'channel'`, `'velocity'`, or `'frequency'`).

### 1.3.5.5 The saveinputs Command

The `saveinputs` command will save the current values of a given task parameters to a Python (plain ascii) file. It can take up to two arguments, e.g.

```
saveinputs(taskname, outfile)
```
CHAPTER 1. INTRODUCTION

Figure 1.2: The clean inputs after setting values away from their defaults (blue text). Note that some of the boldface ones have opened up new dependent sub-parameters (indented and green).

The first is the usual taskname parameter. The second is the name for the output Python file. If there is no second argument, for example,

    saveinputs('clean')

a file with name <taskname>.saved (in this case 'clean.saved' will be created or overwritten if extant. If invoked with no arguments, e.g.

    saveinputs

it will use the current values of the taskname variable (as set using inp <taskname> or default <taskname>). You can also use the taskname global parameter explicitly,

    saveinputs(taskname, taskname+"_1.save")

For example, starting from default values

CASA <1>: default('listobs')
CASA <2>: vis='ngc5921.demo.ms'
CASA <3>: saveinputs
CASA <4>: !more 'listobs.saved'
IPython system call: more 'listobs.saved'
taskname = "listobs"
Figure 1.3: The clean inputs where one parameter has been set to an invalid value. This is drawn in red to draw attention to the problem. This hapless user probably confused the 'hogbom' clean algorithm with Harry Potter.

vis = "ngc5921.demo.ms"
verbose = True
#listobs(vis="ngc5921.ms",verbose=False)

To read these back in, use the Python execfile command. For example,

CASA <5>: execfile('listobs.saved')

and we are back.

An example save to a custom named file:

CASA <6>: saveinputs('listobs', 'ngc5921_listobs.par')

You can also use the CASA tget command (see §1.3.5.6 below) instead of the Python execfile to restore your inputs.

1.3.5.6 The tget Command

The tget command will recover saved values of the inputs of tasks. This is a convenient alternative to using the Python execfile command (see above).
Typing \texttt{tget} without a taskname will recover the saved values of the inputs for the current task as given in the current value of the \texttt{taskname} parameter.

Adding a task name, e.g. \texttt{tget <taskname>} will recover values for the specified task. This is done by searching for 1) a \texttt{<taskname>.last} file (see \S\ 1.3.5.7 below), then for 2) a \texttt{<taskname>.saved} file (see \S\ 1.3.5.5 above), and then executing the Python in these files.

For example,

\begin{verbatim}
  default('gaincal')  # set current task to gaincal and default
  tget               # read saved inputs from gaincal.last (or gaincal.saved)
  inp                # see these inputs!
  tget bandpass      # now get from bandpass.last (or bandpass.saved)
  inp                # task is now bandpass, with recovered inputs
\end{verbatim}

1.3.5.7 The \texttt{.last} file

Whenever you successfully execute a CASA task, a Python script file called \texttt{<taskname>.last} will be written (or over-written) into the current working directory. For example, if you ran the \texttt{listobs} task as detailed above, then

\begin{verbatim}
CASA <14>: vis = 'ngc5921.ms'
CASA <15>: verbose = True
CASA <16>: listobs()
CASA <17>: !more 'listobs.last'
\end{verbatim}

\texttt{IPython system call: more listobs.last}

\begin{verbatim}
taskname   = "listobs"
vis        = "ngc5921.ms"
verbose    = True
#listobs(vis="ngc5921.ms",verbose=False)
\end{verbatim}

You can restore the parameter values from the save file using

\begin{verbatim}
CASA <18>: execfile('listobs.last')
\end{verbatim}

or

\begin{verbatim}
CASA <19>: run listobs.last
\end{verbatim}

Note that the \texttt{.last} file in generally not created until the task actually finished (successfully), so it is often best to manually create a save file beforehand using the \texttt{saveinputs} command if you are running a critical task that you strongly desire to have the inputs saved for.
1.3.6 Tools in CASA

The CASA toolkit is the foundation of the functionality in the package, and consists of a suite of functions that are callable from Python. The tools are used by the tasks, and can be used by advanced users to perform operations that are not available through the tasks.

It is beyond the scope of this Cookbook to describe the toolkit in detail. Occasionally, examples will be given that utilize the tools (e.g. §6.12). In short, tools are always called as functions, with any parameters that are not to be defaulted given as arguments. For example:

```python
ia.open('ngc5921.chan21.clean.cleanbox.mask')
ia.calcmask("ngc5921.chan21.clean.cleanbox.mask">0.5', 'mymask')
ia.summary()
ia.close()
```

uses the image tool (ia) to turn a clean mask image into an image mask. Tools never use the CASA global parameters.

To find what tools are available, use the toolhelp command:

CASA <1>: toolhelp()

Available tools:

- at : Juan Pardo ATM library
- cb : Calibration utilities
- cp : Cal solution plotting utilities
- fg : Flagging/Flag management utilities
- ia : Image analysis utilities
- im : Imaging utilities
- me : Measures utilities
- ms : MeasurementSet (MS) utilities
- mp : MS plotting (data (amp/phase) versus other quantities)
- tb : Table utilities (selection, extraction, etc)
- tp : Table plotting utilities
- qa : Quanta utilities
- sm : Simulation utilities
- vp : Voltage pattern/primary beam utilities

You can find much more information about the toolkit in the CASA User Reference Manual:

[http://casa.nrao.edu/docs/casaref/CasaRef.html](http://casa.nrao.edu/docs/casaref/CasaRef.html)

1.4 Getting the most out of CASA

There are some other general things you should know about using CASA in order to make things go smoothly during your data reduction.
1.4.1 Your command line history

Your command line history is automatically maintained and stored as `ipython.log` in your local directory. This file can be edited and re-executed as appropriate using the `execfile 'filename'` feature.

You can also use the “up-arrow” and “down-arrow” keys for command line recall in the `casapy` interface. If you start typing text, and then use “up-arrow”, you will navigate back through commands matching what you typed.

1.4.2 Logging your session

The output from CASA commands is sent to the file `casapy.log`, also in your local directory. Whenever you start up `casapy`, the previous `casapy.log` is renamed (based on the date and time) and a new log file is started.

![Figure 1.4: The CASA Logger GUI window under Linux. Note that under MacOSX a stripped down logger will instead appear as a Console.](image)

The output contained in `casapy.log` is also displayed in a separate window using the `casalogger`. Generally, the logger window will be brought up when casapy is started. If you do not want the logger GUI to appear, then start casapy using the `--nologger` option,

```
casapy --nologger
```

which will run CASA in the terminal window. See §1.4.2.1 for more startup options.

**BETA ALERT:** Due to problems with Qt under MacOSX, we had to replace the GUI `qtcasalogger` with a special stripped down one that uses the Mac Console. This still has the important capabilities such as showing the messages and cut/paste. The following description is for the Linux version.
CHAPTER 1. INTRODUCTION

Figure 1.5: Using the Search facility in the casalogger. Here we have specified the string ‘plotted’ and it has highlighted all instances in green.

and thus should mostly be disregarded on OSX. On the Mac, you treat this as just another console window and use the usual mouse and hot-key actions to do what is needed.

The CASA logger window for Linux is shown in Figure 1.4. The main feature is the display area for the log text, which is divided into columns. The columns are:

- **Time** — the time that the message was generated. Note that this will be in local computer time (usually UT) for casapy generated messages, and may be different for user generated messages;

- **Priority** — the *Priority Level* (see below) of the message;

- **Origin** — where within CASA the message came from. This is in the format Task::Tool::Method (one or more of the fields may be missing depending upon the message);

- **Message** — the actual text.

The casalogger GUI has a range of features, which include:

- **Search** — search messages by entering text in the Search window and clicking the search icon. The search currently just matches the exact text you type anywhere in the message. See Figure 1.5 for an example.

- **Filter** — a filter to sort by message priority, time, task/tool of origin, and message contents. Enter text in the Filter window and click the filter icon to the right of the window. Use the pull-down at the left of the Filter window to choose what to filter. The matching is for the exact text currently (no regular expressions). See Figure 1.6 for an example.
Figure 1.6: Using the casalogger Filter facility. The log output can be sorted by Priority, Time, Origin, and Message. In this example we are filtering by Origin using ‘clean’, and it now shows all the log output from the clean task.

- **View** — show and hide columns (Time, Priority, Origin, Message) by checking boxes under the View menu pull-down. You can also change the font here.

- **Insert Message** — insert additional comments as “notes” in the log. Enter the text into the “Insert Message” box at the bottom of the logger, and click on the Add (+) button, or choose to enter a longer message. The entered message will appear with a priority of “NOTE” with the Origin as your username. See Figure 1.7 for an example. **BETA ALERT:** This message currently will not be inserted into the correct (or user controllable) order into the log.

- **Copy** — left-click on a row, or click-drag a range of rows, or click at the start and shift click at the end to select. Use the Copy button or Edit menu Copy to put the selected rows into the clipboard. You can then (usually) paste this where you wish. **BETA ALERT:** this does not work routinely in the current version. You are best off going to the casapy.log file if you want to grab text.

- **Open** — There is an Open function in the File menu, and an Open button, that will allow you to load old casalogger files. **BETA ALERT:** You cannot see the old casapy.log files with timestamps (e.g. names like casapy.log-2009-05-26T22:24:31) currently in the file browser, but you can type the name in explicitly and hit <return> to view them.

Other operations are also possible from the menu or buttons. Mouse “flyover” will reveal the operation of buttons, for example.

### 1.4.2.1 Starup options for the logger

One can specify logger options at the startup of casapy on the command line:
CHAPTER 1. INTRODUCTION

Figure 1.7: CASA Logger - Insert facility: The log output can be augmented by adding notes or comments during the reduction. The file should then be saved to disk to retain these changes.

```
casapy <logger option>
```

These options are:

- `--log2term` == logging message go to terminal
- `--nologfile` == no casapy.log logfile is produced
- `--logfile <filename>` == use specified name for logfile instead of casapy.log
- `--nologger` == do not bring up GUI logger (see above)
- `--nolog` (is deprecated use --nologger)

For example, to not bring up a GUI but send the message to your terminal, do

```
casapy --nologger --log2term
```

while

```
casapy --logfile mynewlogfile.log
```

will start casapy with logger messages going to the file mynewlogfile.log.

1.4.2.2 Setting priority levels in the logger

Logger messages are assigned a Priority Level when generated within CASA. The current levels of Priority are:

1. **SEVERE** — errors;
2. **WARN** — warnings;
3. **INFO** — basic information every user should be aware of or has requested;
4. **INFO1** — information possibly helpful to the user;
5. **INFO2** — details the power user might want to see;
6. **INFO3** — even more details;
7. **INFO4** — lowest level of non-debugging information;
8. **DEBUGGING** — most “important” debugging messages;
9. **DEBUG1** — more details;
10. **DEBUG2** — lowest level of debugging messages.

The “debugging” levels are intended for the developers use.

There is a threshold for which these messages are written to the `casapy.log` file and are thus visible in the logger. By default, only messages at level **INFO** and above are logged. The user can change the threshold using the `casalog.filter` method. This takes a single string argument of the **level** for the threshold. The **level** sets the lowest priority that will be generated, and all messages of this level or higher will go into the `casapy.log` file.

Some examples:

```python
from casal import casalog

casalog.filter('INFO')  # the default

casalog.filter('INFO2')  # should satisfy even advanced users

casalog.filter('INFO4')  # all INFOx messages

casalog.filter('DEBUG2')  # all messages including debugging
```

**WARNING:** Setting the threshold to **DEBUG2** will put lots of messages in the log!

**BETA ALERT:** We are transitioning to the new Priority Level system, and not all tasks and tools obey the guidelines uniformly. This will be improved as we progress through the Beta patches. Also, the `casalog` tool is the only way to set the threshold currently.

### 1.4.3 Where are my data in CASA?

Interferometric data are filled into a so-called Measurement Set (or MS). In its logical structure, the MS looks like a generalized description of data from any interferometric or single dish telescope. Physically, the MS consists of several tables in a directory on disk.

Tables in CASA are actually directories containing files that are the sub-tables. For example, when you create a MS called `AM675.ms`, then the name of the directory where all the tables are stored will
be called AM675.ms/. See Chapter 2 for more information on Measurement Set and Data Handling in CASA.

The data that you originally get from a telescope can be put in any directory that is convenient to you. Once you "fill" the data into a measurement set that can be accessed by CASA, it is generally best to keep that MS in the same directory where you started CASA so you can get access to it easily (rather than constantly having to specify a full path name).

When you generate calibration solutions or images (again these are in table format), these will also be written to disk. It is a good idea to keep them in the directory in which you started CASA.

1.4.3.1 How do I get rid of my data in CASA?

Note that when you delete a measurement set, calibration table, or image, which are in fact directories, you must delete this and all underlying directories and files. If you are not running casapy, this is most simply done by using the file delete method of the operating system you started CASA from. For example, when running CASA on a Linux system, in order to delete the measurement set named AM675.ms type:

```
CASA <5>: !rm -r AM675.ms
```

from within CASA. The ! tells CASA that a system command follows (see § 1.2.7.5), and the -r makes sure that all subdirectories are deleted recursively.

It is convenient to prefix all MS, calibration tables, and output files produced in a run with a common string. For example, one might prefix all files from VLA project AM675 with AM675, e.g. AM675.ms, AM675.cal, AM675.clean. Then,

```
CASA <6>: !rm -r AM675*
```

will clean up all of these.

In scripts, the ! escape to the OS will not work. Instead, use the `os.system()` function (Appendix D.6.1) to do the same thing:

```
os.system('rm -r AM675*')
```

If you are within casapy, then the CASA system is keeping a cache of tables that you have been using and using the OS to delete them will confuse things. For example, running a script that contains `rm` commands multiple times will often not run or crash the second time as the cache gets confused. The clean way of removing CASA tables (MS, caltables, images) inside casapy is to use the `rmtables` task:

```
rmtables('AM675.ms')
```

and this can also be wildcarded

```
rmtables('AM675*')
```
BETA ALERT: Some CASA processes lock the file and forget to give it up when they are done (plotxy is usually the culprit. You will get WARNING messages from rmtables and your script will probably crash second time around as the file isn’t removed. The safest thing is still to exit casapy and start a new session for multiple runs.

1.4.4 What’s in my data?

The actual data is in a large MAIN table that is organized in such a way that you can access different parts of the data easily. This table contains a number of “rows”, which are effectively a single timestamp for a single spectral window (like an IF from the VLA) and a single baseline (for an interferometer).

There are a number of “columns” in the MS, the most important of which for our purposes is the DATA column — this contains the original visibility data from when the MS was created or filled. There are other helpful “scratch” columns which hold useful versions of the data or weights for further processing: the CORRECTED_DATA column, which is used to hold calibrated data; the MODEL_DATA column, which holds the Fourier inversion of a particular model image; and the IMAGING_WEIGHT column which can hold the weights to be used in imaging. The creation and use of the scratch columns is generally done behind the scenes, but you should be aware that they are there (and when they are used). We will occasionally refer to the rows and columns in the MS.

More on the contents of the MS can be found in §2.1

1.4.5 Data Selection in CASA

We have tried to make the CASA task interface as uniform as possible. If a given parameter appears in multiple tasks, it should, as far as is possible, mean the same thing and be used in the same way in each. There are groups of parameters that appear in a number of tasks to do the same thing, such as for data selection.

The parameters field, spw, and selectdata (which if True expands to a number of sub-parameters) are commonly used in tasks to select data on which to work. These common data selection parameters are described in §2.6

1.5 From Loading Data to Images

The subsections below provide a brief overview of the steps you will need to load data into CASA and obtain a final, calibrated image. Each subject is covered in more detail in Chapters through 6
An end-to-end workflow diagram for CASA data reduction for interferometry data is shown in Figure 1.8. This might help you chart your course through the package. In the following subsections, we will chart a rough course through this process, with the later chapters filling in the individual boxes.

![Flow chart of the data processing operations that a general user will carry out in an end-to-end CASA reduction session.](image)

Figure 1.8: Flow chart of the data processing operations that a general user will carry out in an end-to-end CASA reduction session.

Note that single-dish data reduction (for example with the ALMA single-dish system) follows a similar course. This is detailed in Chapter A.

1.5.1 Loading Data into CASA

The key data and image import tasks are:
• `importuvfits` — import visibility data in UVFITS format (§2.2.1);
• `importvla` — import data from VLA that is in export format (§2.2.2);
• `importasdm` — import data in ALMA ASDM format (§2.2.3);
• `importfits` — import a FITS image into a CASA image format table (§6.11).

These are used to bring in your interferometer data, to be stored as a CASA Measurement set (MS), and any previously made images or models (to be stored as CASA image tables).

The data import tasks will create a MS with a path and name specified by the `vis` parameter. See §1.4.3 for more information on MS in CASA. The measurement set is the internal data format used by CASA, and conversion from any other native format is necessary for most of the data reduction tasks.

Once data is imported, there are other operations you can use to manipulate the datasets:

• `concat` — concatenate a second MS into a given MS (§2.5)

Data import, export, concatenation, and selection detailed in Chapter 2.

1.5.1.1 VLA: Filling data from VLA archive format

VLA data in “archive” format are read into CASA from disk using the `importvla` task (see §2.2.2). This filler supports the new naming conventions of EVLA antennas when incorporated into the old VLA system.

Note that future data from the EVLA in ASDM format will use a different filler. This will be made available in a later release.

1.5.1.2 Filling data from UVFITS format

For UVFITS format, use the `importuvfits` task. A subset of popular flavors of UVFITS (in particular UVFITS as written by AIPS) is supported by the CASA filler. See §2.2.1 for details.

1.5.1.3 Loading FITS images

For FITS format images, such as those to be used as calibration models, use the `importfits` task. Most, though not all, types of FITS images written by astronomical software packages can be read in.

See §6.11 for more information.
1.5.1.4 Concatenation of multiple MS

Once you have loaded data into measurement sets on disk, you can use the `concat` task to combine them. Currently, `concat` will add a second MS to an existing MS (not producing a new one). This would be run multiple times if you had more than two sets to combine.

See §2.5 for details.

1.5.2 Data Examination, Editing, and Flagging

The main data examination and flagging tasks are:

- `listobs` — summarize the contents of a MS (§2.3);
- `flagmanager` — save and manage versions of the flagging entries in the measurement set (§3.2);
- `flagautocorr` — non-interactive flagging of auto-correlations (§3.3);
- `plotxy` — interactive X-Y plotting and flagging of visibility data (§3.4);
- `flagdata` — non-interactive flagging (and unflagging) of specified data (§3.5);
- `viewer` — the CASA viewer can display (as a raster image) MS data, with some editing capabilities (§7);
- `casaplotms` — a prototype experimental next-generation interactive MS X-Y plotting and flagging tool, that will eventually replace `plotxy` (new in Version 2.4.0) (§3.8).

These tasks allow you to list, plot, and/or flag data in a CASA MS.

There will eventually be tasks for “automatic” flagging to data based upon statistical criteria. Stay tuned.

Examination and editing of synthesis data is described in Chapter 3.

Visualization and editing of an MS using the `casaviewer` is described in Chapter 7.

1.5.2.1 Interactive X-Y Plotting and Flagging

The principal tool for making X-Y plots of visibility data is `plotxy` (see §3.4). Amplitudes and phases (among other things) can be plotted against several x-axis options.

Interactive flagging (i.e., “see it – flag it”) is possible on the `plotxy` X-Y displays of the data (§3.4.5). Since flags are inserted into the measurement set, it is useful to backup (or make a copy) of the current flags before further flagging is done, using `flagmanager` (§3.2). Copies of the flag table can also be restored to the MS in this way.
1.5.2.2 Flag the Data Non-interactively

The `flagdata` task (§ 3.5) will flag the visibility data set based on the specified data selections. The `listobs` task (§ 2.3) may be run (e.g. with `verbose=True`) to provide some of the information needed to specify the flagging scope.

1.5.2.3 Viewing and Flagging the MS

The CASA `viewer` can be used to display the data in the MS as a (grayscale or color) raster image. The MS can also be edited. Use of the `viewer` on an MS is detailed in § 7.4.

1.5.3 Calibration

The major calibration tasks are:

- `setjy` — Computes the model visibilities for a specified source given a flux density or model image, knows about standard calibrator sources (§ 4.3.4);
- `bandpass` — Solves for frequency-dependent (bandpass) complex gains (§ 4.4.2);
- `gaincal` — Solves for time-dependent (frequency-independent) complex gains (§ 4.4.3);
- `fluxscale` — Bootstraps the flux density scale from standard calibrators (§ 4.4.4);
- `polcal` — polarization calibration (§ 4.4.5);
- `accum` — Accumulates incremental calibration solutions into a cumulative calibration table (§ 4.5.4);
- `smoothcal` — Smooths calibration solutions derived from one or more sources (§ 4.5.3);
- `applycal` — Applies calculated calibration solutions (§ 4.6.1);
- `clearcal` — Re-initializes calibrated visibility data in a given measurement set (§ 4.6.3);
- `listcal` — Lists calibration solutions (§ 4.5.2);
- `plotcal` — Plots (and optionally flags) calibration solutions (§ 4.5.1);
- `uvcontsub` — carry out uv-plane continuum subtraction for spectral-line data (§ 4.7.4);
- `split` — write out a new (calibrated) MS for specified sources (§ 4.7.1).

During the course of calibration, the user will specify a set of calibrations to pre-apply before solving for a particular type of effect, for example gain or bandpass or polarization. The solutions are stored in a calibration table (subdirectory) which is specified by the user, *not* by the task: care must be taken in naming the table for future use. The user then has the option, as the calibration process proceeds, to accumulate the current state of calibration in a new cumulative table. Finally, the calibration can be applied to the dataset.

Synthesis data calibration is described in detail in Chapter 4.
1.5.3.1 Prior Calibration

The setjy task places the Fourier transform of a standard calibration source model in the \texttt{MODEL\_DATA} column of the measurement set. This can then be used in later calibration tasks. Currently, setjy knows the flux density as a function of frequency for several standard VLA flux calibrators, and the value of the flux density can be manually inserted for any other source. If the source is not well-modeled as a point source, then a model image of that source structure can be used (with the total flux density scaled by the values given or calculated above for the flux density). Models are provided for the standard VLA calibrators.

Antenna gain-elevation curves (e.g. for the VLA antennas) and atmospheric optical depth corrections (applied as an elevation-dependent function) may be pre-applied before solving for the bandpass and gains. This is currently done by setting the \texttt{gaincurve} and \texttt{opacity} parameters in the various calibration solving tasks.

See §\ref{sec:4.3} for more details.

1.5.3.2 Bandpass Calibration

The bandpass task calculates a bandpass calibration solution: that is, it solves for gain variations in frequency as well as in time. Since the bandpass (relative gain as a function of frequency) generally varies much more slowly than the changes in overall (mean) gain solved for by gaincal, one generally uses a long time scale when solving for the bandpass. The default 'B' solution mode solves for the gains in frequency slots consisting of channels or averages of channels.

A polynomial fit for the solution (solution type 'BPOLY') may be carried out instead of the default frequency-slot based 'B' solutions. This single solution will span (combine) multiple spectral windows.

Bandpass calibration is discussed in detail in §\ref{sec:4.4.2}.

If the gains of the system are changing over the time that the bandpass calibrator is observed, then you may need to do an initial gain calibration (see next step).

1.5.3.3 Gain Calibration

The gaincal task determines solutions for the time-based complex antenna gains, for each spectral window, from the specified calibration sources. A solution interval may be specified. The default 'G' solution mode solved for gains in specified time solution inervals.

A spline fit for the solution (solution type 'GSPLINE') may be carried out instead of the default time-slot based 'G' solutions. This single solution will span (combine) multiple spectral windows.

See §\ref{sec:4.4.3} for more on gain calibration.
1.5.3.4 Polarization Calibration

The `polcal` task will solve for any unknown polarization leakage and cross-hand phase terms (‘D’ and ‘X’ solutions). The ‘D’ leakage solutions will work on sources with no polarization, sources with known (and supplied) polarization, and sources with unknown polarization tracked through a range in parallactic angle on the sky.

The solution for the unknown cross-hand polarization phase difference ‘X’ term requires a polarized source with known linear polarization (Q,U).

See § 4.4.5 for more on polarization calibration.

1.5.3.5 Examining Calibration Solutions

The `plotcal` task (§ 4.5.1) will plot the solutions in a calibration table. The `xaxis` choices include time (for `gaincal` solutions) and channel (e.g. for `bandpass` calibration). The `plotcal` interface and plotting surface is similar to that in `plotxy`. Eventually, `plotcal` will allow you to flag and unflag calibration solutions in the same way that data can be edited in `plotxy`.

The `listcal` task (§ 4.5.2) will print out the calibration solutions in a specified table.

1.5.3.6 Bootstrapping Flux Calibration

The `fluxscale` task bootstraps the flux density scale from “primary” standard calibrators to the “secondary” calibration sources. Note that the flux density scale must have been previously established on the “primary” calibrator(s), typically using `setjy`, and of course a calibration table containing valid solutions for all calibrators must be available.

See § 4.4.4 for more.

1.5.3.7 Calibration Accumulation

The `accum` task applies an incremental solution, of a given type, from a table to a previous calibration table (of the same type), and writes out a cumulative solution table. Different interpolation schemes may be selected.

A description of this process is given in § 4.5.4.

1.5.3.8 Correcting the Data

The final step in the calibration process, `applycal` may be used to apply several calibration tables (e.g., from `gaincal` or `bandpass`). The corrections are applied to the `DATA` column of the visibility, writing the `CORRECTED_DATA` column which can then be plotted (e.g. in `plotxy`), `split` out as the `DATA` column of a new MS, or imaged (e.g. using `clean`). Any existing corrected data are overwritten.
See § 4.6.1 for details.

1.5.3.9 Splitting the Data

After a suitable calibration is achieved, it may be desirable to create one or more new measurement sets containing the data for selected sources. This can be done using the split task (§ 4.7.1).

Further imaging and calibration (e.g. self-calibration) can be carried out on these split Measurement Sets.

1.5.4 Synthesis Imaging

The key synthesis imaging tasks are:

- **clean** — Calculates a deconvolved image based on the visibility data, using one of several clean algorithms (§ 5.3);
- **feather** — Combines a single dish and synthesis image in the Fourier plane (§ 5.5).

Most of these tasks are used to take calibrated interferometer data, with the possible addition of a single-dish image, and reconstruct a model image of the sky.

There are several other utility imaging tasks of interest:

- **makemask** — Makes a mask image from a cleanbox, a file or list specifying sets of pairs of box corners (§ 5.6);
- **ft** — Fourier transforms the specified model (or component list) and inserts this into the MODEL_DATA column of the MS (§ 5.7);
- **deconvolve** — Deconvolve an input image from a provided PSF, using one of several image-plane deconvolution algorithms (§ 5.8).

These are not discussed in this walk-through, see the indicated sections for details.

See Chapter 5 for more on synthesis imaging.

1.5.4.1 Cleaning a single-field image or a mosaic

The CLEAN algorithm is the most popular and widely-studied method for reconstructing a model image based on interferometer data. It iteratively removes at each step a fraction of the flux in the brightest pixel in a defined region of the current “dirty” image, and places this in the model image. The clean task implements the CLEAN algorithm for single-field data. The user can choose from a number of options for the particular flavor of CLEAN to use.
CHAPTER 1. INTRODUCTION

Often, the first step in imaging is to make a simple gridded Fourier inversion of the calibrated data to make a “dirty” image. This can then be examined to look for the presence of noticeable emission above the noise, and to assess the quality of the calibration by searching for artifacts in the image. This is done using clean with niter=0.

The clean task can jointly deconvolve mosaics as well as single fields.

See §5.3 for an in-depth discussion of the clean task.

1.5.4.2 Feathering in a Single-Dish image

If you have a single-dish image of the large-scale emission in the field, this can be “feathered” in to the image obtained from the interferometer data. This is carried out using the feather tasks as the weighted sum in the uv-plane of the gridded transforms of these two images. While not as accurate as a true joint reconstruction of an image from the synthesis and single-dish data together, it is sufficient for most purposes.

See §5.5 for details on the use of the feather task.

1.5.5 Self Calibration

Once a calibrated dataset is obtained, and a first deconvolved model image is computed, a “self-calibration” loop can be performed. Effectively, the model (not restored) image is passed back to another calibration process (on the target data). This refines the calibration of the target source, which up to this point has had (usually) only external calibration applied. This process follows the regular calibration procedure outlined above.

Any number of self-calibration loops can be performed. As long as the images are improving, it is usually prudent to continue the self-calibration iterations.

This process is described in §5.9.

1.5.6 Data and Image Analysis

The key data and image analysis tasks are:

- imhead — summarize and manipulate the “header” information in a CASA image (§6.2);
- imcontsub — perform continuum subtraction on a spectral-line image cube (§6.3);
- immath — perform mathematical operations on or between images (§6.5);
- immoments — compute the moments of an image cube (§6.6);
- imstat — calculate statistics on an image or part of an image (§6.7);
- imregrid — regrid an image onto the coordinate system of another image (§6.9);
• viewer — there are useful region statistics and image cube plotting capabilities in the viewer (§7).

1.5.6.1 What’s in an image?

The imhead task will print out a summary of image “header” keywords and values. This task can also be used to retrieve and change the header values.

See §6.2 for more.

1.5.6.2 Image statistics

The imstat task will print image statistics. There are options to restrict this to a box region, and to specified channels and Stokes of the cube. This task will return the statistics in a Python dictionary return variable.

See §6.7 for more.

1.5.6.3 Moments of an Image Cube

The immoments task will compute a “moments” image of an input image cube. A number of options are available, from the traditional true moments (zero, first, second) and variations thereof, to other images such as median, minimum, or maximum along the moment axis.

See §6.6 for details.

1.5.6.4 Image math

The immath task will allow you to form a new image by mathematical combinations of other images (or parts of images). This is a powerful, but tricky, task to use.

See §6.5 for more.

1.5.6.5 Regridding an Image

It is occasionally necessary to regrid an image onto a new coordinate system. The imregrid task can be used to regrid an input image onto the coordinate system of an existing template image, creating a new output image.

See §6.9 for a description of this task.
1.5.6.6 Displaying Images

To display an image use the `viewer` task. The viewer will display images in raster, contour, or vector form. Blinking and movies are available for spectral-line image cubes. To start the viewer, type:

```
viewer
```

Executing the `viewer` task will bring up two windows: a viewer screen showing the data or image, and a file catalog list. Click on an image or ms from the file catalog list, choose the proper display, and the image should pop up on the screen. Clicking on the wrench tool (second from left on upper left) will obtain the data display options. Most functions are self-documenting.

The viewer can be run outside of casapy by typing `casaviewer`.

See §7 for more on viewing images.

1.5.7 Getting data and images out of CASA

The key data and image export tasks are:

- `exportuvfits` — export a CASA MS in UVFITS format (§2.2.1);
- `exportfits` — export a CASA image table as FITS (§6.11).

These tasks can be used to export a CASA MS or image to UVFITS or FITS respectively. See the individual sections referred to above for more on each.
Chapter 2

Visibility Data Import, Export, and Selection

To use CASA to process your data, you first will need to get it into a form that is understood by the package. These are “measurement sets” for synthesis (and single dish) data, and “image tables” for images.

There are a number of tasks used to fill telescope-specific data, to import/export standard formats, to list data contents, and to concatenate multiple datasets. These are:

- **importuvfits** — import visibility data in UVFITS format (§2.2.1.1)
- **importvla** — import data from VLA that is in export format (§2.2.2)
- **importasdm** — import data in ALMA ASDM format (§2.2.3)
- **exportuvfits** — export a CASA MS in UVFITS format (§2.2.1.2)
- **listobs** — summarize the contents of a MS (§2.3)
- **concat** — concatenate two or more MS into a new MS (§2.5)
- **vishead** — list and change the metadata contents of a MS (§2.4)

In CASA, there is a standard syntax for selection of data that is employed by multiple tasks. This is described in §2.6.

There are also tasks for the import and export of image data using FITS:

- **importfits** — import a FITS image into a CASA image format table (§6.11)
- **exportfits** — export a CASA image table as FITS (§6.11)
2.1 CASA Measurement Sets

Data is handled in CASA via the table system. In particular, visibility data are stored in a CASA table known as a Measurement Set (MS). Details of the physical and logical MS structure are given below, but for our purposes here an MS is just a construct that contains the data. An MS can also store single dish data (essentially a set of auto-correlations of a 1-element interferometer), though there are also data formats more suitable for single-dish spectra (see § A).

Note that images are handled through special image tables, although standard FITS I/O is also supported. Images and image data are described in a separate chapter.

Unless your data was previously processed by CASA or software based upon its predecessor aips++, you will need to import it into CASA as an MS. Supported formats include some “standard” flavors of UVFITS, the VLA “Export” archive format, and most recently, the ALMA Science Data Model (ASDM) format. These are described below in § 2.2.

Once in Measurement Set form, your data can be accessed through various tools and tasks with a common interface. The most important of these is the data selection interface (§ 2.6) which allows you to specify the subset of the data on which the tasks and tools will operate.

2.1.1 Under the Hood: Structure of the Measurement Set

It is not necessary that a casual CASA user know the specific details on how the data in the MS is stored and the contents of all the sub-tables. However, we will occasionally refer to specific “columns” of the MS when describing the actions of various tasks, and thus we provide the following synopsis to familiarize the user with the necessary nomenclature. You may skip ahead to subsequent sections if you like!

All CASA data files, including Measurement Sets, are written into the current working directory by default, with each CASA table represented as a separate sub-directory. MS names therefore need only comply with UNIX file or directory naming conventions, and can be referred to from within CASA directly, or via full path names.

An MS consists of a MAIN table containing the visibility data, and associated sub-tables containing auxiliary or secondary information. The tables are logical constructs, with contents located in the physical table.* files on disk. The MAIN table consists of the table.* files in the main directory of the ms-file itself, and the other tables are in the respective subdirectories. The various MS tables and sub-tables can be seen by listing the contents of the MS directory itself (e.g. using Unix ls), or via the browsetable task (§ 3.6).

See Fig 2.1 for an example of the contents of a MS directory. Or, from the casapy prompt,
CHAPTER 2. VISIBILITY DATA IMPORT, EXPORT, AND SELECTION

CASA <1>: ls ngc5921.ms
IPython system call: ls -F ngc5921.ms
ANTENNA POLARIZATION table.f1 table.f3_TSM1 table.f8
DATA_DESCRIPTION PROCESSOR table.f10 table.f4 table.f8_TSM1
FEED SORTED_TABLE table.f10_TSM1 table.f5 table.f9
FIELD SOURCE table.f11 table.f5_TSM1 table.f9_TSM1
FLAG_CMD SPECTRAL_WINDOW table.f11_TSM1 table.f6 table.info
HISTORY STATE table.f2 table.f6_TSM0 table.lock
OBSERVATION table.dat table.f2_TSM1 table.f7
POINTING table.f0 table.f3 table.f7_TSM1

Note that the MAIN table information is contained in the table.* files in this directory. Each of the sub-table sub-directories contain their own table.dat and other files, e.g.

CASA <2>: ls ngc5921.ms/SOURCE
IPython system call: ls -F ngc5921.ms/SOURCE
table.dat table.f0 table.f0i table.info table.lock

Figure 2.1: The contents of a Measurement Set. These tables compose a Measurement Set named ngc5921.demo.ms on disk. This display is obtained by using the File:Open menu in browsetable and left double-clicking on the ngc5921.demo.ms directory.
Each “row” in a table contains entries for a number of specified “columns”. For example, in the MAIN table of the MS, the original visibility data is contained in the DATA column — each “cell” contains a matrix of observed complex visibilities for that row at a single time stamp, for a single baseline in a single spectral window. The shape of the data matrix is given by the number of channels and the number of correlations (voltage-products) formed by the correlator for an array.

Table 2.1 lists the non-data columns of the MAIN table that are most important during a typical data reduction session. Table 2.2 lists the key data columns of the MAIN table of an interferometer MS. The MS produced by fillers for specific instruments may insert special columns, such as ALMA_PHASE_CORR, ALMA_NO_PHASE_CORR and ALMA_PHASE_CORR_FLAG_ROW for ALMA data filled using the importasdm filler (§ 2.2.3). These columns are visible in browsetable and are accessible from the toolkit in the ms tool (e.g. the ms.getdata method) and from the tb “table” tool (e.g. using tb.getcol).

Note that when you examine table entries for IDs such as FIELD_ID or DATA_DESC_ID, you will see 0-based numbers.

Table 2.1: Common columns in the MAIN table of the MS.

<table>

</tr>
</tbody>
</table>

The MS can contain a number of “scratch” columns, which are used to hold useful versions of other columns such as the data or weights for further processing. The most common scratch columns are:

- **CORRECTED_DATA** — used to hold calibrated data for imaging or display;
- **MODEL_DATA** — holds the Fourier inversion of a particular model image for calibration or imaging;
- **IMAGING_WEIGHT** — holds the gridding weights to be used in imaging.

The creation and use of the scratch columns is generally done behind the scenes, but you should be aware that they are there (and when they are used).
Table 2.2: Commonly accessed MAIN Table data-related columns. Note that the columns ALMA\_PHASE\_CORR, ALMA\_NO\_PHAS\_CORR and ALMA\_PHAS\_CORR\_FLAG\_ROW are specific to ALMA data filled using the importasdm filler.

</table>

The most recent specification for the MS is Aips++ MeasurementSet definition version 2.0 [http://casa.nrao.edu/Memos/229.html](http://casa.nrao.edu/Memos/229.html).

### 2.2 Data Import and Export

There are a number of tasks available to bring data in various forms into CASA as a Measurement Set:

- UVFITS format can be imported into and exported from CASA (importuvfits and exportuvfits)
- VLA Archive format data can be imported into CASA (importvla)
- ALMA and EVLA Science Data Model format data can be imported into CASA (importasdm)

#### 2.2.1 UVFITS Import and Export

The UVFITS format is not exactly a standard, but is a popular archive and transport format nonetheless. CASA supports UVFITS files written by the AIPS FITTP task, and others. UVFITS is supported for both import and export.
2.2.1.1 Import using importuvfits

To import UVFITS format data into CASA, use the importuvfits task:

```casa
importuvfits(fitsfile='NGC5921.fits', vis='ngc5921.ms')
```

**BETA ALERT:** We cannot currently fill CARMA data exported via Miriad UVFITS.

2.2.1.2 Export using exportuvfits

The exportuvfits task will take a MS and write it out in UVFITS format. The defaults are:

```casa
exportuvfits(vis='ngc5921.split.ms', fitsfile='NGC5921.split.fits',
             multisource=False)
```

The MS selection parameters `field`, `spw`, `antenna`, and `timerange` follow the standard selection syntax described in §2.6.

**BETA ALERT:** The `nchan`, `start`, and `width` parameters will be superseded by channel selection in `spw`. Currently, there is a `time` parameter rather than `timerange`.

The `datacolumn` parameter chooses which data-containing column of the MS (see §2.1.1) is to be written out to the UV FITS file. Choices are: `data`, `corrected`, and `model`.

There are a number of special parameters that control what is written out. These are mostly here for compatibility with AIPS.

The `writeyscal` parameter toggles whether GC and TY extension tables are written. These are important for VLBA data, and for EVLA data. **BETA ALERT:** Not yet available.

The `multisource` parameter determines whether the UV FITS file is a multi-source file or a single-source file, if you have a single-source MS or choose only a single source. Note: the difference between a single-source and multi-source UVFITS file here is whether it has a source (SU) table and the source ID in the random parameters. If you select more than one source in `fields`, then the `multisource` parameter will be overridden to be `True` regardless.

The `combinespw` parameter allows combination of all spectral windows at one time. If `True`, then all spectral windows must have the same shape. For AIPS to read an exported file, then set `combinespw=True`.

The `writestation` parameter toggles the writing of the station name instead of antenna name.

### 2.2.2 VLA: Filling data from archive format (importvla)

VLA data in archive format (i.e., as downloaded from the VLA data archive) are read into CASA from disk using the `importvla` task. The inputs are:

```
# importvla :: import VLA archive file(s) to a measurement set:

archivefiles = '' # Name of input VLA archive file(s)
vis = '' # Name of output visibility file
bandname = '' # VLA frequency band name: ''=>obtain all bands in archive files
frequencytol = 150000.0 # Frequency shift to define a unique spectral window (Hz)
project = '' # Project name: ''=> all projects in file
starttime = '' # start time to search for data
stoptime = '' # end time to search for data
applytsys = True # apply nominal sensitivity scaling to data & weights
autocorr = False # import autocorrelations to ms, if set to True
antnamescheme = 'new' # 'old' or 'new'; 'VA04' or '4' for ant 4
keepblanks = False # Fill scans with empty source names (e.g. tipping scans)?
async = False
```

The main parameters are `archivefiles` to specify the input VLA Archive format file names, and `vis` to specify the output MS name.
BETA ALERT:  The scaling of VLA data both before and after the June 2007 Modcomp-turnoff is fully supported, based on the value of `applytsys`.

The NRAO Archive is located at:

- [https://archive.nrao.edu](https://archive.nrao.edu)

Note that `archivefiles` takes a string or list of strings, as there are often multiple files for a project in the archive.

For example:

```python
archivefiles = ['AP314_A950519.xp1','AP314_A950519.xp2']
vis = 'NGC7538.ms'
```

The `importvla` task allows selection on the frequency band. Suppose that you have 1.3 cm line observations in K-band and you have copied the archive data files `AP314_A95019.xp*` to your working directory and started `casapy`. Then,

```python
default('importvla')
archivefiles = ['AP314_A950519.xp1','AP314_A950519.xp2','AP314_A950519.xp3']
vis = 'ngc7538.ms'
bandname = 'K'
frequencytol = 10e6
importvla()
```

If the data is located in a different directory on disk, then use the full path name to specify each archive file, e.g.:

```python
archivefiles=['/home/rohir2/jmcmulli/ALMATST1/Data/N7538/AP314_A950519.xp1',
'/home/rohir2/jmcmulli/ALMATST1/Data/N7538/AP314_A950519.xp2',
'/home/rohir2/jmcmulli/ALMATST1/Data/N7538/AP314_A950519.xp3']
```

Important Note: `importvla` will import the on-line flags (from the VLA system) along with the data. These will be put in the MAIN table and thus available to subsequent tasks and tools. If you wish to revert to unflagged data, use `flagmanager` (§ 3.2) to save the flags (if you wish), and then use `flagdata` (§ 3.5) with `mode='manualflag'` and `unflag=True` to toggle off the flags.

The other parameters are:

### 2.2.2.1 Parameter `applytsys`

The `applytsys` parameter controls whether the nominal sensitivity scaling (based on the measured TSYS, with the weights scaled accordingly using the integration time) is applied to the visibility amplitudes or not. If `True`, then it will be scaled so as to be the same as AIPS `FILLM` (ie. approximately in deciJanskys). Note that post-Modcomp data is in raw correlation coefficient and will be scaled using the TSYS values, while Modcomp-era data had this applied online. In all cases
importvla will do the correct thing to data and weights based on an internal flag in the VLA Archive file, either scaling it or unscaling based on your choice for applytsys.

If applytsys=True and you see strange behavior in data amplitudes, it may be due to erroneous TSYS values from the online system. You might want to then fill with applytsys=False and look at the correlation coefficients to see if the behavior is as expected.

2.2.2.2 Parameter bandname

The bandname indicates the VLA Frequency band(s) to load, using the traditional bandname codes. These are:

- ’4’ = 48-96 MHz
- ’P’ = 298-345 MHz
- ’L’ = 1.15-1.75 GHz
- ’C’ = 4.2-5.1 GHz
- ’X’ = 6.8-9.6 GHz
- ’U’ = 13.5-16.3 GHz
- ’K’ = 20.8-25.8 GHz
- ’Q’ = 38-51 GHz
- ’’ = all bands (default)

Note that as the transition from the VLA to EVLA progresses, the actual frequency ranges covered by the bands will expand, and additional bands will be added (namely ’S’ from 1-2 GHz and ’A’ from 26.4-40 GHz).

2.2.2.3 Parameter frequencytol

The frequencytol parameter specifies the frequency separation tolerated when assigning data to spectral windows. The default is frequencytol=150000 (Hz). For Doppler tracked data, where the sky frequency changes with time, a frequencytol < 10000 Hz may produce too many unnecessary spectral windows.

2.2.2.4 Parameter project

You can specify a specific project name to import from archive files. The default ’’ will import data from all projects in file(s) archivefiles.

For example for VLA Project AL519:
CHAPTER 2. VISIBILITY DATA IMPORT, EXPORT, AND SELECTION

```python
project = 'AL519'  # this will work
project = 'al519'  # this will also work
```

while `project='AL0519'` will NOT work (even though that is what queries to the VLA Archive will print it as - sorry!).

### 2.2.2.5 Parameters `starttime` and `stoptime`

You can specify start and stop times for the data, e.g.:

```python
starttime = '1970/1/31/00:00:00'
stoptime = '2199/1/31/23:59:59'
```

Note that the blank defaults will load all data fitting other criteria.

### 2.2.2.6 Parameter `autocorr`

Note that autocorrelations are filled into the data set if `autocorr=True`. Generally for the VLA, autocorrelation data is not useful, and furthermore the imaging routine will try to image the autocorrelation data (it assumes it is single dish data) which will swamp any real signal. Thus, if you do fill the autocorrelations, you will have to flag them before imaging.

### 2.2.2.7 Parameter `antnamescheme`

The `antnamescheme` parameter controls whether `importvla` will try to use a naming scheme where EVLA antennas are prefixed with `EA` (e.g. `'EA16'`) and old VLA antennas have names prefixed with `VA` (e.g. `'VA11'`). Our method to detect whether an antenna is EVLA is not yet perfected, and thus unless you require this feature, simply use `antnamescheme='old'`.

### 2.2.3 ALMA: Filling ALMA Science Data Model (ASDM) observations

The `importasdm` task will fill an ASDM into a CASA visibility data set (MS).

**BETA ALERT**: Note that ASDM data are not generally available at this time, except for commissioning at the ALMA Test Facility (ATF) and the site. Thus, this filler is in a development stage. Also, currently there are no options for filling selected data (you get the whole data set).

Current inputs are:

```bash
# importasdm :: Convert an ALMA Science Data Model observation into a CASA visibility file
asdm = '' # Name of input asdm directory (on disk)
corr_mode = 'all' # Correlation mode on input (e.g. 'ao' 'co' 'ac')
srt = 'all' # Spectral resolution type on input (e.g. 'fr' 'ca' 'bw')
time_sampling = 'all' # Time sampling (INTEGRATION 'i' and/or SUBINTEGRATION 'si')
```
For example:

CASA <1>: importasdm('/home/basho3/jmcmulli/ASDM/ExecBlock3')

Parameter: asdm is: /home/basho3/jmcmulli/ASDM/ExecBlock3 and has type <type 'str'>.
Taking the dataset /home/basho3/jmcmulli/ASDM/ExecBlock3 as input.
Time spent parsing the XML medata :1.16 s.
The measurement set will be filled with complex data

2.3 Summarizing your MS (listobs)

Once you import your data into a CASA Measurement Set, you can get a summary of the MS contents with the listobs task.

The inputs are:

```python
vis = '' # Name of input visibility file (MS)
verbose = True # Extended summary list of data set in logger
```

The summary will be written to the logger and to the casapy.log file. For example, using verbose=False:

```python
listobs('n5921.ms',False)
```

results in the logger messages:

```
Thu Jul 5 17:20:55 2007 NORMAL ms::summary:

Thu Jul 5 17:23:55 2007 NORMAL ms::summary ""

Thu Jul 5 17:23:55 2007 NORMAL ms::close:
ReadOnly measurement set: just detaching from file.

The most useful extra information that verbose=True gives is the list of the scans in the dataset.

2.4 Listing and manipulating MS metadata (vishead)

BETA ALERT: This is still a prototype task.

The default inputs are:

```python
# vishead :: List, get, and put metadata in a measurement set
vis = '' # Name of input visibility file
mode = 'summary' # options: list, summary, get, put
async = False #
```

For mode = 'list' the options are: 'telescope', 'observer', 'project', 'field', 'freq_group_name', 'spw_name', 'schedule', 'schedule_type', 'release_date'.

2.5 Concatenating multiple datasets (concat)

Once you have your data in the form of CASA Measurement Sets, you can go ahead and process your data using the editing, calibration, and imaging tasks. In some cases, you will most efficiently operate on single MS for a particular session (such as calibration). Other tasks will (eventually) take multiple Measurement Sets as input. For others, it is easiest to combine your multiple data files into one.

If you need to combine multiple datasets, you can use the concat task. The default inputs are:
# concat :: Concatenate two or more visibility data sets.

vis = [''] # Name of input visibility files to be concatenated
concatvis = '' # Name of output visibility file
freqtol = '' # Frequency tolerance for considering data as the same spwid
dirtol = '' # Direction tolerance for considering data as the same field
timemort = False # If true, sort by TIME in ascending order
async = False # If true the taskname must be started using concat(...)

The `vis` parameter will take a list of one or more MS. Usually, this will contain all the MS to combine.

The `concatvis` parameter contains the name of the output MS. If this points to an existing file on disk, then the MS in `vis` will appended to it, otherwise a new MS file is created to contain the concatenated data. Be careful here!

The parameters `freqtol` and `dirtol` control how close together in frequency and angle on the sky spectral windows or field locations need to be before calling them the same.

**BETA ALERT:** Note that if multiple frequencies or pointings are combined using `freqtol` or `dirtol`, then the data are not changed (ie. not rephased to the single phase center). Use of these parameters is intended to be tolerant of small offsets (e.g. planets tracked which move slightly in J2000 over the course of observations, or combining epochs observed with slightly different positions).

For example:

```
default('concat')
vis = ['n4826_16apr.split.ms','n4826_22apr.split.ms']
concatvis = 'n4826_tboth.ms'
freqtol = '50MHz'
concat()
```

combines the two days in `n4826_16apr.split.ms` and `n4826_22apr.split.ms` into a new output MS called `n4826_tboth.ms`.

**BETA ALERT:** There are additional issues when concatenating individual MS files with different spectral windows. In this case, the rest frequencies (if set) of these windows may be lost in subsequent operations (e.g. `split`). If this occurs, then you can either set the `restfreq` explicitly in certain tasks (`plotxy` and `clean`), or use the following snippet of code to fix this up after `concat` has run:

```
# # Fix up the MS after concat (NOTE: STILL NECESSARY IN 2.4)
# This ensures that the rest freq will be found for all spws.
# print '---Fixing up spw rest frequencies in MS---'
vis='ngc4826.tutorial.ms' # Example vis name, put yours here!
tb.open(vis+'/SOURCE',nomodify=false)
spwid=tb.getcol('SPECTRAL_WINDOW_ID')
```
# The following is for 64bit systems 08-Jul-2008. ok on 32bit also.
spwid.setfield(-1,'int32')
tb.putcol('SPECTRAL_WINDOW_ID', spwid)
tb.close()

For example, this is used in the NGC4826 BIMA mosaic script (Appendix F.3).

## 2.6 Data Selection

Once in MS form, subsets of the data can be operated on using the tasks and tools. In CASA, there are three common data selection parameters used in the various tasks: `field`, `spw`, and `selectdata`. In addition, the `selectdata` parameter, if set to `True`, will open up a number of other sub-parameters for selection. The selection operation is unified across all the tasks. The available `selectdata` parameters may not be the same in all tasks. But if present, the same parameters mean the same thing and behave in the same manner when used in any task.

For example:

```plaintext
field = '' # field names or index of calibrators ''==>all
spw = '' # spectral window:channels: ''==>all
selectdata = False # Other data selection parameters
```

versus

```plaintext
field = '' # field names or index of calibrators ''==>all
spw = '' # spectral window:channels: ''==>all
selectdata = True # Other data selection parameters
timerange = '' # time range: ''==>all
uvrange = '' # uv range''=all
antenna = '' # antenna/baselines: ''==>all
scan = '' # scan numbers: Not yet implemented
msselect = '' # Optional data selection (Specialized. but see help)
```

The following are the general syntax rules and descriptions of the individual selection parameters of particular interest for the tasks:

### 2.6.1 General selection syntax

Most of the selections are effected through the use of selection strings. This sub-section describes the general rules used in constructing and parsing these strings. Note that some selections are done
CHAPTER 2. VISIBILITY DATA IMPORT, EXPORT, AND SELECTION

92

though the use of numbers or lists. There are also parameter-specific rules that are described under each parameter.

All lists of basic selection specification-units are comma separated lists and can be of any length. White-spaces before and after the commas (e.g. '3C286, 3C48, 3C84') are ignored, while white-space within sub-strings is treated as part of the sub-string (e.g. '3C286, VIRGO A, 3C84').

All integers can be of any length (in terms of characters) composed of the characters 0–9. Floating point numbers can be in the standard format (DIGIT.DIGIT, DIGIT., or .DIGIT) or in the mantissa-exponent format (e.g. 1.4e9). Places where only integers make sense (e.g. IDs), if a floating point number is given, only the integer part is used (it is truncated).

Range of numbers (integers or real numbers) can be given in the format 'N0~N1'. For integer ranges, it is expanded into a list of integers starting from N0 (inclusive) to N1 (inclusive). For real numbers, it is used to select all values present for the appropriate parameter in the Measurement Set between N0 and N1 (including the boundaries). Note that the '~' character is used rather than the more obvious '-' in order to accommodate hyphens in strings and minus signs in numbers.

Wherever appropriate, units can be specified. The units are used to convert the values given to the units used in the Measurement Set. For ranges, the unit is specified only once (at the end) and applies to both the range boundaries.

2.6.1.1 String Matching

String matching can be done in three ways. Any component of a comma separated list that cannot be parsed as a number, a number range, or a physical quantity is treated as a regular expression or a literal string. If the string does not contain the characters '*', '{', '}' or '?', it is treated as a literal string and used for exact matching. If any of the above mentioned characters are part of the string, they are used as a regular expression. As a result, for most cases, the user does not need to supply any special delimiters for literal strings and/or regular expressions. For example:

```plaintext
field = '3'       # match field ID 3 and not select field named "3C286".

field = '3*'      # used as a pattern and matched against field names. If
                 # names like "3C84", "3C286", "3020+2207" are found,
                 # all will match. Field ID 3 will not be selected
                 # (unless of course one of the above mentioned field
                 # names also correspond to field ID 3!).

field = '30*'     # will match only with "3020+2207" in above set.
```

However if it is required that the string be matched exclusively as a regular expression, it can be supplied within a pair of '/' as delimiters (e.g. '/\.+BAND.+/'). A string enclosed within double quotes ('"') is used exclusively for pattern matching (patterns are a simplified form of regular expressions - used in most UNIX commands for string matching). Patterns are internally converted to equivalent regular expressions before matching. See the Unix command "info regex", or visit [http://www.regular-expressions.info](http://www.regular-expressions.info) for details of regular expressions and patterns.

Strings can include any character except the following:
(since these are part of the selection syntax). Strings that do not contain any of the characters used to construct regular expressions or patterns are used for exact matches. Although it is highly discouraged to have name in the MS containing the above mentioned reserved characters, if one does choose to include the reserved characters as parts of names etc., those names can only be matched against quoted strings (since regular expression and patterns are a super-set of literal strings – i.e., a literal string is also a valid regular expression).

This leaves ‘”’, ‘*’, ‘{‘, ‘}’ or ‘?’ as the list of printable character that cannot be part of a name (i.e., a name containing this character can never be matched in a MSSelection expression). These will be treated as pattern-matching even inside double double quotes (" "). There is currently no escape mechanism (e.g. via a backslash).

Some examples of strings, regular expressions, and patterns:

- The string ‘LBAND’ will be used as a literal string for exact match. It will match only the exact string LBAND.
- The wildcarded string ‘*BAND*’ will be used as a string pattern for matching. This will match any string which has the sub-string BAND in it.
- The string ‘"*BAND"’ will also be used as a string pattern, matching any string which has the sub-string BAND in it.
- The string ‘/.+BAND.+/' will be used as a regular expression. This will also match any string which as the sub-string BAND in it. (the .+ regex operator has the same meaning as the * wildcard operator of patterns).

2.6.2 The field Parameter

The field parameter is a string that specifies which field names or ids will be processed in the task or tool. The field selection expression consists of comma separated list of field specifications inside the string.

Field specifications can be literal field names, regular expressions or patterns (see §2.6.1.1). Those fields for which the entry in the NAME column of the FIELD MS sub-table match the literal field name/regular expression/pattern are selected. If a field name/regular expression/pattern fails to match any field name, the given name/regular expression/pattern are matched against the field code. If still no field is selected, an exception is thrown.

Field specifications can also be given by their integer IDs. IDs can be a single or a range of IDs. Field ID selection can also be done as a boolean expression. For a field specification of the form ‘>ID’, all field IDs greater than ID are selected. Similarly for ‘<ID’ all field IDs less than the ID are selected.

For example, if the MS has the following observations:
CHAPTER 2. VISIBILITY DATA IMPORT, EXPORT, AND SELECTION

MS summary:

<table>
<thead>

one might select

- \texttt{field = '0,1,2,KTIP'} # FIELDid 0,1,2 and field name KTIP
- \texttt{field = '0530+135'} # field 0530+135
- \texttt{field = '05*'} # fields 0530+135, 05582+16320, 05309+13319

2.6.3 The \texttt{spw} Parameter

The \texttt{spw} parameter is a string that indicates the specific spectral windows and the channels within them to be used in subsequent processing. Spectral window selection (\texttt{SPWSEL}) can be given as a spectral window integer ID, a list of integer IDs, a spectral window name specified as a literal string (for exact match) or a regular expression or pattern.

The specification can be via frequency ranges or by indexes. A range of frequencies are used to select all spectral windows which contain channels within the given range. Frequencies can be specified with an optional unit — the default unit being Hz. Other common choices for radio and mm/sub-mm data are kHz, MHz, and GHz. You will get the entire spectral windows, not just the channels in the specified range. You will need to do channel selection (see below) to do that.

The \texttt{spw} can also be selected via comparison for integer IDs. For example, \texttt{'>ID'} will select all spectral windows with ID greater than the specified value, while \texttt{'<ID'} will select those with ID lesser than the specified value.

**BETA ALERT:** In the current Beta Release, \texttt{'<ID'} and \texttt{'>ID'} are \textit{inclusive} with the ID specified included in the selection, e.g. \texttt{spw='<2'} is equivalent to \texttt{spw='0,1,2'} and not \texttt{spw='0,1'} as was intended. This will be fixed in an upcoming release.

Spectral window selection using strings follows the standard rules:

\begin{verbatim}
spw = '1'   # SPWID 1
spw = '1,3,5' # SPWID 1,3,5
spw = '0~3'   # SPWID 0,1,2,3
spw = '0~3,5' # SPWID 0,1,2,3 and 5
spw = '<3,5'  # SPWID 0,1,2,3 and 5
spw = '*'     # All spectral windows
spw = '1412~1415MHz' # Spectral windows containing 1412-1415MHz
\end{verbatim}

In some cases, the spectral windows may allow specification by name. For example,
might be meaningful for the dataset in question.

Note that the order in which multiple spw values are given may be important for other parameters. For example, the mode = 'channel' in clean uses the first spw as the origin for the channelization of the resulting image cube.

### 2.6.3.1 Channel selection in the spw parameter

Channel selection can be included in the spw string in the form 'SPWSEL:CHANSEL' where CHANSEL is the channel selector. In the end, the spectral selection within a given spectral window comes down to the selection of specific channels. We provide a number of shorthand selection options for this. These CHANSEL options include:

- **Channel ranges**: 'START~STOP'
- **Frequency ranges**: 'FSTART~FSTOP'
- **Velocity ranges**: 'VSTART~VSTOP' (not yet available)
- **Bandwidth percentages**: 'PSTART~PSTOP' or 'PWIDTH' (not yet available)
- **Channel striding/stepping**: 'START~STOP^STEP' or 'FSTART~FSTOP^FSTEP'

The most common selection is via channel ranges 'START~STOP' or frequency ranges 'FSTART~FSTOP':

```plaintext
spw = '0:13~53'  # spw 0, channels 13-53, inclusive
spw = '0:1413~1414MHz'  # spw 0, 1413-1414MHz section only
```

All ranges are inclusive, with the channel given by, or containing the frequency or velocity given by, START and STOP plus all channels between included in the selection. You can also select the spectral window via frequency ranges 'FSTART~FSTOP', as described above:

```plaintext
spw = '1413~1414MHz:1413~1414MHz'  # channels falling within 1413~1414MHz
spw = '*:1413~1414MHz'  # does the same thing
```

You can also specify multiple spectral window or channel ranges, e.g.

```plaintext
spw = '2:16, 3:32~34'  # spw 2, channel 16 plus spw 3 channels 32-34
spw = '2:1~3;57~63'  # spw 2, channels 1-3 and 57-63
spw = '1~3:10~20'  # spw 1-3, channels 10-20
spw = '*:4~56'  # all spw, channels 4-56
```
Note the use of the wildcard in the last example.

A step can be also be included using ‘\^STEP’ as a postfix:

\[
\begin{align*}
\text{spw} &= \text{’0:10\textasciitilde100\textasciitilde2’} & \text{# chans 10,12,14,…,100 of spw 0} \\
\text{spw} &= \text{’:\textasciitilde4’} & \text{# chans 0,4,8,… of all spw} \\
\text{spw} &= \text{’:100\textasciitilde150GHz\textasciitilde10GHz’} & \text{# closest chans to 100,110,…,150GHz}
\end{align*}
\]

A step in frequency or velocity will pick the channel in which that frequency or velocity falls, or the nearest channel.

### 2.6.4 The `selectdata` Parameters

The `selectdata` parameter, if set to `True`, will expand the inputs to include a number of sub-parameters, given below and in the individual task descriptions (if different). If `selectdata = False`, then the sub-parameters are treated as blank for selection by the task. The default for `selectdata` is `False`.

The common `selectdata` expanded sub-parameters are:

### 2.6.4.1 The `antenna` Parameter

The `antenna` selection string is a semi-colon (’;’) separated list of baseline specifications. A baseline specification is of the form:

- ‘\texttt{ANT1}’ — Select all baselines including the antenna(s) specified by the selector \texttt{ANT1}.
- ‘\texttt{ANT1&}’ — Select only baselines between the antennas specified by the selector \texttt{ANT1}.
- ‘\texttt{ANT1&ANT2}’ — Select only the cross-correlation baselines between the antennas specified by selector \texttt{ANT1} and antennas specified by selector \texttt{ANT2}. Thus ‘\texttt{ANT1&}’ is an abbreviation for ‘\texttt{ANT1&ANT1}’.
- ‘\texttt{ANT1&&ANT2}’ — Select only auto-correlation and cross-correlation baselines between antennas specified by the selectors \texttt{ANT1} and \texttt{ANT2}. Note that this is what the default \texttt{antenna=’} gives you.
- ‘\texttt{ANT1&&&}’ — Select only autocorrelations specified by the selector \texttt{ANT1}.

The selectors \texttt{ANT1} and \texttt{ANT2} are comma-separated lists of antenna integer-IDs or literal antenna names, patterns, or regular expressions. The \texttt{ANT} strings are parsed and converted to a list of antenna integer-IDs or IDs of antennas whose name match the given names/pattern/regular expression. Baselines corresponding to all combinations of the elements in lists on either side of ampersand are selected.
CHAPTER 2. VISIBILITY DATA IMPORT, EXPORT, AND SELECTION

Integer IDs can be specified as single values or a range of integers. When items of the list are parsed as literal strings or regular expressions or patterns (see §2.6.1 for more details on strings). All antenna names that match the given string (exact match)/regular expression/pattern are selected.

The comma is used only as a separator for the list of antenna specifications. The list of baselines specifications is a semi-colon separated list, e.g.

\[
\text{antenna = '1~3 & 4~6 ; 10&11'}
\]

will select baselines between antennas 1,2,3 and 4,5,6 ('1&4', '1&5', ..., '3&6') plus baseline '10&11'.

The wildcard operator ('*') will be the most often used pattern. To make it easy to use, the wildcard (and only this operator) can be used without enclosing it in quotes. For example, the selection

\[
\text{antenna = 'VA*'}
\]

will match all antenna names which have 'VA' as the first 2 characters in the name (irrespective of what follows after these characters).

Some examples:

\[
\begin{align*}
\text{antenna} & = '1', \quad \text{# shows blank autocorr pages} \\
\text{antenna} & = '*&*', \quad \text{# does not show the autocorrs} \\
\text{antenna} & = '*&&&*', \quad \text{# show both auto and cross-cor (default)} \\
\text{antenna} & = '*&&&', \quad \text{# shows only autocorrs} \\
\text{antenna} & = '5&*', \quad \text{# shows non-auto baselines with AN 5} \\
\text{antenna} & = '5,6&&&', \quad \text{# AN 5 and 6 autocor} \\
\text{antenna} & = '5&&&;6&*', \quad \text{# AN 5 autocor plus cross-cor to AN 6}
\end{align*}
\]

Antenna numbers as names: Needless to say, naming antennas such that the names can also be parsed as a valid token of the syntax is a bad idea. Nevertheless, antenna names that contain any of the reserved characters and/or can be parsed as integers or integer ranges can still be used by enclosing the antenna names in double quotes (' "ANT" '). E.g. the string

\[
\text{antenna = '10~15,21,VA22'}
\]

will expand into an antenna ID list 10,11,12,13,14,15,21,22 (assuming the index of the antenna named 'VA22' is 22). If the antenna with ID index 50 is named '21', the string

\[
\text{antenna = '10~15,"21",VA22'}
\]

will expand into an antenna ID list of 10,11,12,13,14,15,50,22.

Read elsewhere (e.g. info regex under Unix) for details of regular expression and patterns.
2.6.4.2 The scan Parameter

The scan parameter selects the scan ID numbers of the data. There is currently no naming convention for scans. The scan ID is filled into the MS depending on how the data was obtained, so use this with care.

Examples:

scan = '3' # scan number 3.
scan = '1~8' # scan numbers 1 through 8, inclusive
scan = '1,2,4,6' # scans 1,2,4,6
scan = '<9' # scans <9 (1-8)

NOTE: ALMA and VLA/EVLA number scans starting with 1 and not 0. You can see what the numbering is in your MS using the listobs task with verbose=True (see § 2.3).

2.6.4.3 The timerange Parameter

The time strings in the following (T0, T1 and dT) can be specified as YYYY/MM/DD/HH:MM:SS.FF. The time fields (i.e., YYYY, MM, DD, HH, MM, SS and FF), starting from left to right, may be omitted and they will be replaced by context sensitive defaults as explained below.

Some examples:

1. timerange='T0~T1': Select all time stamps from T0 to T1. For example:

   timerange = '2007/10/09/00:40:00 ~ 2007/10/09/03:30:00'

   Note that fields missing in T0 are replaced by the fields in the time stamp of the first valid row in the MS. For example,

   timerange = '09/00:40:00 ~ 09/03:30:00'

   where the YY/MM/ part of the selection has been defaulted to the start of the MS. Fields missing in T1, such as the date part of the string, are replaced by the corresponding fields of T0 (after its defaults are set). For example:

   timerange = '2007/10/09/22:40:00 ~ 03:30:00'

   does the same thing as above.

2. timerange='T0': Select all time stamps that are within an integration time of T0. For example,

   timerange = '2007/10/09/23:41:00'

   Integration time is determined from the first valid row (more rigorously, an average integration time should be computed). Default settings for the missing fields of T0 are as in (1).
3. \texttt{timerange}='T0+dT': Select all time stamps starting from \(T0\) and ending with time stamp \(T0+dT\). For example,

\[
\texttt{timerange} = \ '23:41:00+01:00:00'
\]

picks an hour-long chunk of time.

Defaults of \(T0\) are set as usual. Defaults for \(dT\) are set from the time corresponding to MJD=0. Thus, \(dT\) is a specification of length of time from the assumed nominal "start of time".

4. \texttt{timerange}='\textgreater T0': Select all times greater than \(T0\). For example,

\[
\texttt{timerange} = \ '\textgreater 2007/10/09/23:41:00'
\]

Default settings for \(T0\) are as above.

5. \texttt{timerange}='\textless T1': Select all times less than \(T1\). For example,

\[
\texttt{timerange} = \ '\textless 2007/10/09/23:41:00'
\]

Default settings for \(T1\) are as above.

An ultra-conservative selection might be:

\[
\texttt{timerange} = \ '1960/01/01/00:00:00\textasciitilde2020/12/31/23:59:59'
\]

which would choose all possible data!

\subsection{2.6.4.4 The uvrange Parameter}

Rows in the MS can also be selected based on the uv-distance or physical baseline length that the visibilities in each row correspond to. This \texttt{uvrange} can be specified in various formats.

The basic building block of uv-distance specification is a valid number with optional units in the format \(N\{UNIT\}\) (the unit in square brackets is optional). We refer to this basic building block as \texttt{UVDIST}. The default unit is meter. Units of length (such as \textquoteleft m\textquoteright\ and \textquoteleft km\textquoteright) select physical baseline distances (independent of wavelength). The other allowed units are in wavelengths (such as \textquoteleft \lambda\textquoteright, \textquoteleft k\lambda\textquoteright\ and \textquoteleft M\lambda\textquoteright\ and are true uv-plane radii

\[
r_{uv} = \sqrt{u^2 + v^2}.
\] (2.1)

If only a single \texttt{UVDIST} is specified, all rows, the uv-distance of which exactly matches the given \texttt{UVDIST}, are selected.

\texttt{UVDIST} can be specified as a range in the format \textquoteleft N0\textasciitildeN1\{UNIT\}' (where \textasciitilde\ and \{UNIT\} are valid numbers). All rows corresponding to uv-distance between \(N0\) and \(N1\) (inclusive) when converted the specified units are selected.
UVDIST can also be selected via comparison operators. When specified in the format ‘>UVDIST’, all visibilities with uv-distances greater than the given UVDIST are selected. Likewise, when specified in the format ‘<UVDIST’, all rows with uv-distances less than the given UVDIST are selected.

Any number of above mentioned uv-distance specifications can be given as a comma-separated list. Examples:

- `uvrange = ’100~200km’` # an annulus in physical baseline length
- `uvrange = ’24~35Mlambda, 40~45Mlambda’` # two annuli in units of mega-wavelengths
- `uvrange = ’< 45klambda’` # less than 45 kilolambda
- `uvrange = ’> 0klambda’` # greater than zero length (no auto-corrs)
- `uvrange = ’100klambda’` # baselines of length 100km
- `uvrange = ’100klambda’` # uv-radius 100 kilolambda

### 2.6.4.5 The `msselect` Parameter

More complicated selections within the MS structure are possible using the Table Query Language (TaQL). This is accessed through the `msselect` parameter.

Note that the TaQL syntax does not follow the rules given in §2.6.1 for our other selection strings. TaQL is explained in more detail in Aips++ NOTE 199 — Table Query Language (http://aips2.nrao.edu/docs/notes/199/199.html). This will eventually become a CASA document. The specific columns of the MS are given in the most recent MS specification document: Aips++ NOTE 229 — MeasurementSet definition version 2.0 (http://aips2.nrao.edu/docs/notes/229/229.html). This documentation will eventually be updated to the CASA document system.

Most selection can be carried out using the other selection parameters. However, these are merely shortcuts to the underlying TaQL selection. For example, field and spectral window selection can be done using `msselect` rather than through `field` or `spw`:

- `msselect=’FIELD_ID == 0’` # Field id 0 only
- `msselect=’FIELD_ID <= 1’` # Field id 0 and 1
- `msselect=’FIELD_ID IN [1,2]’` # Field id 1 and 2
- `msselect=’FIELD_ID==0 && DATA_DESC_ID==3’` # Field id 0 in spw id 3 only

**BETA ALERT:** The `msselect` style parameters will be phased out of the tasks. TaQL selection will still be available in the Toolkit.
Chapter 3

Data Examination and Editing

3.1 Plotting and Flagging Visibility Data in CASA

The tasks available for plotting and flagging of data are:

- **flagmanager** — manage versions of data flags (§3.2)
- **flagautocorr** — non-interactive flagging of auto-correlations (§3.3)
- **plotxy** — create X-Y plots of data in MS, flag data (§3.4)
- **flagdata** — non-interactive flagging of data (§3.5)
- **browsetable** — browse data in any CASA table (including a MS) (§3.6)
- **plotants** — create simple plots of antenna positions (§3.7)
- **casaplotms** — prototype next-generation X-Y MS plotter (experimental) (§3.8)

The following sections describe the use of these tasks.

Information on other related operations can be found in:

- **listobs** — list what’s in a MS (§2.3)
- **selectdata** — general data selection syntax (§2.6)
- **viewer** — use the casaviewer to display the MS as a raster image, and flag it (§7)
3.2 Managing flag versions with flagmanager

The flagmanager task will allow you to manage different versions of flags in your data. These are stored inside a CASA flagversions table, under the name of the MS <msname>.flagversions. For example, for the MS jupiter6cm.usecase.ms, there will need to be jupiter6cm.usecase.ms.flagversions on disk. This is created on import (by importvla or importuvfits) or when flagging is first done on an MS without a .flagversions (e.g. with plotxy).

By default, when the .flagversions is created, this directory will contain a flags.Original in it containing a copy of the original flags in the MAIN table of the MS so that you have a backup. It will also contain a file called FLAG_VERSION_LIST that has the information on the various flag versions there.

The inputs for flagmanager are:

- **vis** = '' # Name of input visibility file (MS)
- **mode** = 'list' # Flag management operation (list,save,restore,delete)

The mode='list' option will list the available flagversions from the <msname>.flagversions file. For example:

```python
casa <102>: default('flagmanager')
casa <103>: vis = 'jupiter6cm.usecase.ms'
casa <104>: mode = 'list'
casa <105>: flagmanager()
```

MS : /home/imager-b/smyers/Oct07/jupiter6cm.usecase.ms
main : working copy in main table
Original : Original flags at import into CASA
flagautocorr : flagged autocorr
xyflags : Plotxy flags

The mode parameter expands the options. For example, if you wish to save the current flagging state of vis=<msname>,

- **mode** = 'save' # Flag management operation (list,save,restore,delete)
- **versionname** = '' # Name of flag version (no spaces)
- **comment** = '' # Short description of flag version
- **merge** = 'replace' # Merge option (replace, and, or)

with the output version name specified by versionname. For example, the above xyflags version was written using:

```python
default('flagmanager')
vis = 'jupiter6cm.usecase.ms'
mode = 'save'
versionname = 'xyflags'
comment = 'Plotxy flags'
flagmanager()
```
and you can see that there is now a sub-table in the flagversions directory

CASA <106>: ls jupiter6cm.usecase.ms.flagversions/
IPython system call: ls -F jupiter6cm.usecase.ms.flagversions/
flags.flagautocorr flags.Original flags.xyflags FLAG_VERSION_LIST

It is recommended that you use this facility regularly to save versions during flagging.
You can restore a previously saved set of flags using the mode='restore' option:

```python
mode = 'restore' # Flag management operation (list,save,restore,delete)
versionname = '' # Name of flag version (no spaces)
merge = 'replace' # Merge option (replace, and, or)
```

The merge sub-parameter will control the action. For merge='replace', the flags in versionname will replace those in the MAIN table of the MS. For merge='and', only data that is flagged in BOTH the current MAIN table and in versionname will be flagged. For merge='or', data flagged in EITHER the MAIN or in versionname will be flagged.

The mode='delete' option can be used to remove versionname from the flagversions:

```python
mode = 'delete' # Flag management operation (list,save,restore,delete)
versionname = '' # Name of flag version (no spaces)
```

### 3.3 Flagging auto-correlations with flagautocorr

The flagautocorr task can be used if all you want to do is to flag the auto-correlations out of the MS. Nominally, this can be done upon filling from the VLA for example, but you may be working from a dataset that still has them.

This task has a single input, the MS file name:

```ini
vis = '' # Name of input visibility file (MS)
```

To use it, just set and go:

```python
CASA <90>: vis = 'jupiter6cm.usecase.ms'
CASA <91>: flagautocorr()
```

Note that the auto-correlations can also be flagged using flagdata (§3.5) but the flagautocorr task is an handy shortcut for this common operation.

### 3.4 X-Y Plotting and Editing of the Data

**BETA ALERT:** The plotxy code is fragile and slow, and is being replaced by the casaplotms tool (§3.8). A prototype version of that application is available in Version 2.4.0.
The principal way to get X-Y plots of visibility data is using the \texttt{plotxy} task. This task also provides editing capability. CASA uses the \texttt{matplotlib} plotting library to display its plots. You can find information on \texttt{matplotlib} at \url{http://matplotlib.sourceforge.net/}.

Figure 3.1: The \texttt{plotxy} plotter, showing the Jupiter data versus uv-distance. You can see bad data in this plot. The \textbf{bottom set of buttons} on the lower left are: 1) \textbf{Home}, 2) \textbf{Back}, and 3) \textbf{Forward}. Click to navigate between previously defined views (akin to web navigation). 4) \textbf{Pan}. Click and drag to pan to a new position. 5) \textbf{Zoom}. Click to define a rectangular region for zooming. 6) \textbf{Subplot Configuration}. Click to configure the parameters of the subplot and spaces for the figures. 7) \textbf{Save}. Click to launch a file save dialog box. The \textbf{upper set of buttons in the lower left} are: 1) \textbf{Mark Region}. Press this to begin marking regions (rather than zooming or panning). 2,3,4) \textbf{Flag, Unflag, Locate}. Click on these to flag, unflag, or list the data within the marked regions. 5) \textbf{Next}. Click to move to the next in a series of iterated plots. Finally, the \textbf{cursor readout} is on the bottom right.
To bring up this plotter use the `plotxy` task. The inputs are:

```python
# plotxy :: X-Y plotter/interactive flagger for visibility data

vis = ''     # Name of input visibility
xaxis = 'time' # X-axis: def = 'time': see help for options
yaxis = 'amp' # Y-axis: def = 'amp': see help for options
datacolumn = 'data' # data (raw), corrected, model, residual (corrected - model)

selectdata = False # Other data selection parameters
spw = ''     # spectral window: channels: 'all, spw='1:5~57'
field = ''    # field names or index of calibrators: 'all'
averagemode = 'vector' # Select averaging type: vector, scalar
timebin = '0'  # Length of time-interval in seconds to average
crossscans = False # Have time averaging cross scan boundaries?
crossbls = False # have averaging cross over baselines?
crossarrays = False # have averaging cross over arrays?
stackspw = False # stack multiple spw on top of each other?
width = '1'   # Number of channels to average

restfreq = ''     # a frequency quanta or transition name. see help for options
extendflag = False # Have flagging extend to other data points?
subplot = 111     # Panel number on display screen (yxn)
plotsymbol = '.'   # Options include . : , o ^ v > < s + x D d 2 3 4 h H | _
plotcolor = 'darkcyan' # Plot color
plotrange = [-1, -1, -1, -1] # The range of data to be plotted (see help)
multicolor = 'corr' # Plot in different colors: Options: none, both, chan, corr
selectplot = False # Select additional plotting options (e.g, fontsize, title,etc)
overplot = False # Overplot on current plot (if possible)
showflags = False # Show flagged data?
interactive = True # Show plot on gui?
figfile = '' # no plot hardcopy, otherwise supply name
async = False # if True the taskname must be started using plotxy(...)

**BETA ALERT:** The `plotxy` task expects all of the scratch columns to be present in the MS, even if it is not asked to plot the contents. If you get an error to the effect "Invalid Table operation: Table: cannot add a column" then use `clearcal()` to force these columns to be made in the MS. Note that this will clear anything in all scratch columns (in case some were actually there and being used).

Setting `selectdata=True` opens up the selection sub-parameters:

```python
selectdata = True # Other data selection parameters
antenna = ''     # antenna/baselines: 'all, antenna = '3,VA04'
timerange = ''    # time range: 'all
 correlation = ''  # correlations: default = ''
 scan = ''        # scan numbers: Not yet implemented
 feed = ''        # multi-feed numbers: Not yet implemented
 array = ''       # array numbers: Not yet implemented
 uvrange = ''     # uv range; 'all; uvrange = '0~100kl' (default unit=meters)```
These are described in §2.6.

Averaging is controlled with the set of parameters

- **averagemode**: 'vector'  # Select averaging type: vector, scalar
- **timebin**: '0'  # Length of time-interval in seconds to average
- **crossscans**: False  # Have time averaging cross scan boundaries?
- **crossbls**: False  # Have averaging cross over baselines?
- **crossarrays**: False  # Have averaging cross over arrays?
- **stackspw**: False  # Stack multiple spw on top of each other?
- **width**: '1'  # Number of channels to average

Note that the `timebin`, `crossscans`, and `width` sub-parameters are always open and available whether `averagemode='vector'` or `'scalar'`. See §3.4.4 below for more on averaging.

You can extend the flagging beyond the data cell plotted:

- **extendflag**: True  # Have flagging extend to other data points?
- **extendcorr**:  # flagging correlation extension type
- **extendchan**:  # flagging channel extension type
- **extendspw**:  # flagging spectral window extension type
- **extendant**:  # flagging antenna extension type
- **extendtime**:  # flagging time extension type

See §3.4.6 below for more on flag extension.

The `restfreq` parameter can be set to a transition or frequency:

- **restfreq**: 'HI'  # a frequency quanta or transition name. see help for options
- **frame**: 'LSRK'  # frequency frame for spectral axis. see help for options
- **doppler**: 'RADIO'  # doppler mode. see help for options

See §3.4.7 below for more on setting rest frequencies and frames.

Setting `selectplot=True` will open up a set of plotting control sub-parameters. These are described in §3.4.2 below.

The `interactive` and `figfile` parameters allow non-interactive production of hardcopy plots. See §3.4.8 for more details on saving plots to disk.

The `iteration`, `overplot`, `plotrange`, `plotsymbol`, `showflags` and `subplot` parameters deserve extra explanation, and are described in §3.4.3 below.

For example:

```python
plotxy(vis='jupiter6cm.ms',  # jupiter 6cm dataset
       xaxis='uvdist',  # plot uv-distance on x-axis
       yaxis='amp',  # plot amplitude on y-axis
       field='JUPITER',  # plot only JUPITER
       selectdata=True,  # open data selection
       correlation='RR,LL',  # plot RR and LL correlations
       selectplot=True,  # open plot controls
       title = 'Jupiter 6cm uncalibrated')  # give it a title
```
The plotter resulting from these settings is shown in figure 3.1.

**BETA ALERT:** The plotxy task still has a number of issues. The averaging has been greatly speeded up in this release, but there are cases where the plots will be made incorrectly. In particular, there are problems plotting multiple spw at the same time. There are sometimes also cases where data that you have flagged in plotxy from averaged data is done so incorrectly. This task is under active development for the next cycle to fix these remaining problems, so users should be aware of this.

**BETA ALERT:** Another known problem with (plotxy) is that it fails if the path to your working directory contains spaces in its name, e.g. /users/smyers/MyTest/ is fine, but /users/smyers/MyTest/ is not!

### 3.4.1 GUI Plot Control

You can use the various buttons on the plotxy GUI to control its operation – in particular, to determine flagging and unflagging behaviors.

There is a standard row of buttons at the bottom. These include (left to right):

- **Home** — The “house” button (1st on left) returns to the original zoom level.
- **Step** — The left and right arrow buttons (2nd and 3rd from left) step through the zoom settings you’ve visited.
- **Pan** — The “four-arrow button” (4th from left) lets you pan in zoomed plot.
- **Zoom** — The most useful is the “magnifying glass” (5th from the left) which lets you draw a box and zoom in on the plot.
- **Panels** — The “window-thingy” button (second from right) brings up a menu to adjust the panel placement in the plot.
- **Save** — The “disk” button (last on right) saves a .png copy of the plot to a generically named file on disk.

In a row above these, there are a set of other buttons (left to right):

- **Mark Region** — If depressed lets you draw rectangles to mark points in the panels. This is done by left-clicking and dragging the mouse. You can Mark multiple boxes before doing something. Clicking the button again will un-depress it and forget the regions. ESC will remove the last region marked.
- **Flag** — Click this to Flag the points in a marked region.
- **Unflag** — Click this to Unflag any flagged point that would be in that region (even if invisible).
• **Locate** — Print out some information to the logger on points in the marked regions.

• **Next** — Step to the next plot in an iteration.

• **Quit** — Exit `plotcal`, clear the window and detach from the MS.

These buttons are shared with the `plotcal` tool.

### 3.4.2 The `selectplot` Parameters

These parameters work in concert with the native matplotlib functionality to enable flexible representations of data displays.

Setting `selectplot=True` will open up a set of plotting control sub-parameters:

```python
selectplot = True # Select additional plotting options (e.g., fontsize, title, etc)
markersize = 5.0 # Size of plotted marks
linewidth = 1.0 # Width of plotted lines
skiprows = 1 # Plot every nth point
newplot = False # Replace the last plot or not when overplotting
clearpanel = 'Auto' # Specify if old plots are cleared or not
title = '' # Plot title (above plot)
xlabels = '' # Label for x-axis
ylabels = '' # Label for y-axis
fontsize = 10.0 # Font size for labels
windowsize = 5.0 # Window size: not yet implemented
```

The `markersize` parameter will change the size of the plot symbols. Increasing it will help legibility when doing screen shots. Decreasing it can help in congested plots. The `linewidth` parameter will do similar things to the lines.

The `skiprows` parameter, if set to an integer \( n \) greater than 1, will allow only every \( n \)th point to be plotted. It does this, as the name suggests, by skipping over whole rows of the MS, so beware (channels are all within the same row for a given `spw`). Be careful flagging on data where you have skipped points! Note that you can also reduce the number of points plotted via averaging (§3.4.4) or channel striding in the `spw` specification (§2.6.3).

The `newplot` toggle lets you choose whether or not the last layer plotted is replaced when `overplot=True`, or whether a new layer is added.

The `clearpanel` parameter turns on/off the clearing of plot panels that lie under the current panel layer being plotted. The options are: 'none' (clear nothing), 'auto' (automatically clear the plotting area), 'current' (clear the current plot area only), and 'all' (clear the whole plot panel).

The `title`, `xlabels`, and `ylabels` parameters can be used to change the plot title and axes labels.

---

**Inside the Toolkit:**

For even more functionality, you can access the `pl` tool directly using `pylab` functions that allow one to annotate, alter, or add to any plot displayed in the `matplotlib` plotter (e.g. `plotxy`).

---
The `fontsize` parameter is useful in order to enlarge the label fonts so as to be visible when making plots for screen capture, or just to improve legibility. Shrinking can help if you have lots of panels on the plot also.

The `windowsize` parameter is supposed to allow adjustments on the window size. **BETA ALERT:** This currently does nothing, unless you set it below 1.0, in which case it will produce an error.

### 3.4.3 Plot Control Parameters

The `iteration`, `overplot`, `plotrange`, `plotsymbol`, `showflags` and `subplot` parameters deserve extra explanation:

#### 3.4.3.1 iteration

There are currently four iteration options available: `field`, `antenna`, and `baseline`. If one of these options is chosen, the data will be split into separate plot displays for each value of the iteration axis (e.g., for the VLA, the 'antenna' option will get you 27 displays, one for each antenna).

**BETA ALERT:** There will eventually be 'scan' and 'feed' options also.

An example use of iteration:

```python
# choose channel averaging, every 5 channels
plotxy('n5921.ms','channel',subplot=221,iteration='antenna',width='5')
```

The results of this are shown in Figure 3.2. Note that this example combines the use of `width`, `iteration` and `subplot`.

**NOTE:** If you use `iteration='antenna'` or `baseline`, be aware if you have set antenna selection. You can also control whether you see auto-correlations or not using the appropriate syntax, e.g. `antenna='*&&*` or `antenna='*&&'` ($2.6.4.1$).

#### 3.4.3.2 overplot

The `overplot` parameter toggles whether the current plot will be overlaid on the previous plot or subpanel (via the `subplot` setting, § section:edit.plot.opt.subplot) or will overwrite it. The default is `False` and the new plot will replace the old.

The `overplot` parameter interacts with the `newplot` sub-parameter (see § 3.4.2).

See § 3.4.3.5 for an example using `overplot`.  

Figure 3.2: The plotxy iteration plot. The first set of plots from the example in §3.4.3.1 with iteration=’antenna’. Each time you press the Next button, you get the next series of plots.

3.4.3.3 plotrange

The plotrange parameter can be used to specify the size of the plot. The format is [xmin, xmax, ymin, ymax]. The units are those on the plot. For example,

plotrange = [-20,100,15,30]

Note that if xmin=xmax and/or ymin=ymax, then the values will be ignored and a best guess will be made to auto-range that axis. BETA ALERT: Unfortunately, the units for the time axis must be in Julian Days, which are the plotted values.
3.4.3.4 plotsymbol

The plotsymbol parameter defines both the line or symbol for the data being drawn as well as the color; from the matplotlib online documentation (e.g., type `pl.plot?` for help):

The following line styles are supported:

- : solid line
-- : dashed line
-. : dash-dot line
.: : dotted line
. : points
, : pixels
o : circle symbols
^- : triangle up symbols
v : triangle down symbols
< : triangle left symbols
> : triangle right symbols
s : square symbols
+ : plus symbols
x : cross symbols
D : diamond symbols
d : thin diamond symbols
1 : tripod down symbols
2 : tripod up symbols
3 : tripod left symbols
4 : tripod right symbols
h : hexagon symbols
H : rotated hexagon symbols
p : pentagon symbols
| : vertical line symbols
_ : horizontal line symbols

steps : use gnuplot style 'steps' # kwarg only

The following color abbreviations are supported

b : blue
g : green
r : red
c : cyan
m : magenta
y : yellow
k : black
w : white

In addition, you can specify colors in many weird and wonderful ways, including full names 'green', hex strings '#008000', RGB or RGBA tuples (0,1,0,1) or grayscale intensities as a string '0.8'. Line styles and colors are combined in a single format string, as in 'bo' for blue circles.
3.4.3.5 showflags

The showflags parameter determines whether only unflagged data (showflags=False) or flagged (showflags=True) data is plotted by this execution. The default is False and will show only unflagged “good” data.

Note that if you want to plot both unflagged and flagged data, in different colors, then you need to run plotxy twice using overplot (see §3.4.3.2) the second time, e.g.

> plotxy(vis="myfile", xaxis='uvdist', yaxis='amp' )
> plotxy(vis="myfile", xaxis='uvdist', yaxis='amp', overplot=True, showflags=True )

3.4.3.6 subplot

The subplot parameter takes three numbers. The first is the number of y panels (stacking vertically), the second is the number of x panels (stacking horizontally) and the third is the number of the panel you want to draw into. For example, subplot=212 would draw into the lower of two panels stacked vertically in the figure.

An example use of subplot capability is shown in Fig 3.3. These were drawn with the commands (for the top, bottom left, and bottom right panels respectively):

```
plotxy('n5921.ms','channel', # plot channels for the n5921.ms data set
       field='0', # plot only first field
       datacolumn='corrected', # plot corrected data
       plotcolor='', # over-ride default plot color
       plotsymbol='go', # use green circles
       subplot=211) # plot to the top of two panels

plotxy('n5921.ms','x', # plot antennas for n5921.ms data set
       field='0', # plot only first field
       datacolumn='corrected', # plot corrected data
       subplot=223, # plot to 3rd panel (lower left) in 2x2 grid
       plotcolor='', # over-ride default plot color
       plotsymbol='r.' ) # red dots

plotxy('n5921.ms','u','v', # plot uv-coverage for n5921.ms data set
       field='0', # plot only first field
       datacolumn='corrected', # plot corrected data
       subplot=224, # plot to the lower right in a 2x2 grid
       plotcolor='', # over-ride default plot color
       plotsymbol='b,' ) # blue, somewhat larger dots
# NOTE: You can change the gridding
# and panel size by manipulating
# the ny x nx grid.
```

See also §3.4.3.1 above, and Figure 3.2 for an example of channel averaging using iteration and subplot.
CHAPTER 3. DATA EXAMINATION AND EDITING

Figure 3.3: Multi-panel display of visibility versus channel (top), antenna array configuration (bottom left) and the resulting uv coverage (bottom right). The commands to make these three panels respectively are: 1) `plotxy('ngc5921.ms', xaxis='channel', datacolumn='data', field='0', subplot=211, plotcolor='', plotsymbol='go')` 2) `plotxy('ngc5921.ms', xaxis='x', field='0', subplot=223, plotsymbol='r.')`, 3) `plotxy('ngc5921.ms', xaxis='u', yaxis='v', field='0', subplot=224, plotsymbol='b,', figfile='ngc5921_multiplot.png').

3.4.4 Averaging in plotxy

The averaging parameters and sub-parameters are:

- `averagemode` = 'vector' # Select averaging type: vector, scalar
- `timebin` = '0' # length of time in seconds to average, default='0', or: 'all'
- `crossscans` = False # have time averaging cross over scans?
- `crossbls` = False # have averaging cross over baselines?
The choice of `averagemode` controls how the amplitudes are calculated in the average. The default mode is `'vector'`, where the complex average is formed by averaging the real and imaginary parts of the relevant visibilities. If `'scalar'` is chosen, then the amplitude of the average is formed by a scalar average of the individual visibility amplitudes.

Time averaging is effected by setting the `timebin` parameter to a value larger than the integration time. Currently, `timebin` takes a string containing the averaging time in seconds, e.g.

```python
timebin = '60.0'
```

to plot one-minute averages.

Channel averaging is invoked by setting `width` to a value greater than 1. Currently, the averaging `width` is given as a number of channels.

By default, the averaging will not cross scan boundaries (as set in the import process). However, if `crossscans=True`, then averaging will cross scans.

Note that data taken in different sub-arrays are never averaged together. Likewise, there is no way to plot data averaged over field.

### 3.4.5 Interactive Flagging in `plotxy`

Interactive flagging, on the principle of “see it — flag it”, is possible on the X-Y display of the data plotted by `plotxy`. The user can use the cursor to mark one or more regions, and then flag, unflag, or list the data that falls in these zones of the display.

There is a row of buttons below the plot in the window. You can punch the `Mark Region` button (which will appear to depress), then mark a region by left-clicking and dragging the mouse (each click and drag will mark an additional region). You can get rid of all your regions by clicking again on the `Mark Region` button (which will appear to un-depress), or you can use the `ESC` key to remove the last box you drew. Once regions are marked, you can then click on one of the other buttons to take action:

1. **Flag** — flag the points in the region(s),
2. **Unflag** — unflag flagged points in the region(s),
3. **Locate** — spew out a list of the points in the region(s) to the logger (Warning: this could be a long list!).

Hint!

In the plotting environments such as `plotxy`, the `ESC` key can be used to remove the last region box drawn.
Whenever you click on a button, that action occurs without forcing a disk-write (unlike previous versions). If you quit plotxy and re-enter, you will see your previous edits.

A table with the name \(<\text{msname}>.\text{flagversions}\) (where \(\text{vis}<\text{msname}>\)) will be created in the same directory if it does not exist already.

It is recommended that you save important flagging stages using the \texttt{flagmanager} task (§3.2).

### 3.4.6 Flag extension in plotxy

Flag extension is controlled using \texttt{extendflag=T} and its sub-parameters:

```plaintext
extendflag        = True    # Have flagging extend to other data points?
extendcorr       = ''      # flagging correlation extension type
extendchan       = ''      # flagging channel extension type
extendspw        = ''      # flagging spectral window extension type
extendant        = ''      # flagging antenna extension type
extendtime       = ''      # flagging time extension type
```

The use of \texttt{extendflag} enables the user to plot a subset of the data and extend the flagging to a wider set.

**BETA ALERT:** Using the \texttt{extendflag} options will greatly slow down the flagging in plotxy. You will see a long delay after hitting the \texttt{Flag} button, with lots of logger messages as it goes through each flag. Fixing this requires a refactoring of \texttt{plotxy} which is underway starting in Patch 4 development.
Setting `extendchan='all'` will extend the flagging to other channels in the same spw as the displayed point. For example, if `spw='0:0'` and channel 0 is displayed, then flagging will extend to all channels in spw 0.

The `extendcorr` sub-parameter will extend the flagging beyond the correlations displayed. If `extendcorr='all'`, then all correlations will be flagged, e.g. with RR displayed RR,RL,LR,LL will be flagged. If `extendcorr='half'`, then the extension will be to those correlations in common with that show, e.g. with RR displayed then RR,RL,LR will be flagged.

Setting `extendspw='all'` will extend the flagging to all other spw for the selection. Using the same example as above, with `spw='0:0'` displayed, then channel 0 in ALL spw will be flagged. Note that use of `extendspw` could result in unintended behavior if the spw have different numbers of channels, or if it is used in conjunction with `extendchan`.

**WARNING:** use of the following options, particularly in conjunction with other flag extensions, may lead to deletion of much more data than desired. Be careful!

Setting `extendant='all'` will extend the flagging to all baselines that have antennas in common with those displayed and marked. For example, if `antenna='1&2'` is shown, then ALL baselines to BOTH antennas 1 and 2 will be flagged. Currently, there is no option to extend the flag to ONLY baselines to the first (or second) antenna in a displayed pair, so it is better to use `flagdata` to remove specific antennas.

Setting `extendtime='all'` will extend the flagging to all times matching the other selection or extension for the data in the marked region.

### 3.4.7 Setting rest frequencies in `plotxy`

The `restfreq` parameter can be set to a transition or frequency and expands to allow setting of frame information. For example,

```r
restfreq = 'HI'  # a frequency quanta or transition name. see help for options
frame = 'LSRK'  # frequency frame for spectral axis. see help for options
doppler = 'RADIO'  # doppler mode. see help for options
```

Examples of transitions include:

- `restfreq='1420405751.786Hz'`  # 21cm HI frequency
- `restfreq='HI'`  # 21cm HI transition name
- `restfreq='115.2712GHz'`  # CO 1-0 line frequency

For a list of known lines in the CASA `measures` system, use the toolkit command `me.linelist()`. For example:

```r
CASA <14>: me.linelist()
```
CHAPTER 3. DATA EXAMINATION AND EDITING

BETA ALERT: The list of known lines in CASA is currently very restricted, and will be increased in upcoming releases (to include lines in ALMA bands for example).

You can use the `me.spectralline` tool method to turn transition names into frequencies

```plaintext
CASA <16>: me.spectralline('HI')
Out[17]:
{'m0': {'unit': 'Hz', 'value': 1420405751.786},
 'refer': 'REST',
 'type': 'frequency'}
```

(not necessary for this task, but possibly useful).

The `frame` sub-parameter sets the frequency frame. The allowed options can be listed using the `me.listcodes` method on the `me.frequency()` method, e.g.

```plaintext
CASA <17>: me.listcodes(me.frequency())
Out[17]:
{'extra': array([],
 dtype='|S1'),
 'normal': array(['REST', 'LSRK', 'LSRD', 'BARY', 'GEO', 'TOPO', 'GALACTO', 'LGROUP',
 'CMB'],
 dtype='|S8')}
```

The `doppler` sub-parameter likewise sets the Doppler system. The allowed codes can be listed using the `me.listcodes` method on the `me.doppler()` method,

```plaintext
CASA <18>: me.listcodes(me.doppler())
Out[18]:
{'extra': array([],
 dtype='|S1'),
 'normal': array(['RADIO', 'Z', 'RATIO', 'BETA', 'GAMMA', 'OPTICAL', 'TRUE',
 'RELATIVISTIC'],
 dtype='|S13')}
```

For most cases the `RADIO` Doppler system is appropriate, but be aware of differences.

For more information on frequency frames and spectral coordinate systems, see the paper by Greisen et al. (A&A, 446, 747, 2006) [1]

### 3.4.8 Printing from plotxy

There are two ways to get hardcopy plots in `plotxy`.

The first is to use the “disk save” icon from the interactive plot GUI to print the current plot. This will bring up a sub-menu GUI that will allow you to choose the filename and format. The allowed formats are .png (PNG), .eps (EPS), and svg (SVG). If you give the filename with a suffix (.png,
.eps, or svg) it will make a plot of that type. Otherwise it will put a suffix on depending on the format chosen from the menu.

**BETA ALERT:** The plot files produced by the EPS option can be large, and the SVG files can be very large. The PNG is the smallest.

The second is to specify a figfile. You probably want to disable the GUI using interactive=False in this case. The type of plot file that is made will depend upon the filename suffix. The allowed choices are .png (PNG), .eps (EPS), and svg (SVG).

This latter option is most useful from scripts. For example,

```python
default('plotxy')
vis = 'ngc5921.ms'
field = '2'
spw = ''
xaxis = 'uvdist'
yaxis = 'amp'
interactive=False
figfile = 'ngc5921.uvplot.amp.png'
plotxy()
```

will plot amplitude versus uv-distance in PNG format. No plotxy GUI will appear.

**BETA ALERT:** if you use this option to print to figfile with an iteration set, you will only get the first plot.

### 3.4.9 Exiting plotxy

You can use the Quit button to clear the plot from the window and detach from the MS. You can also dismiss the window by killing it with the X on the frame, which will also detach the MS.

You can also just leave it alone. The plotter pretty much keeps running in the background even when it looks like it’s done! You can keep doing stuff in the plotter window, which is where the overplot parameter comes in. Note that the plotcal task (§4.5.1) will use the same window, and can also overplot on the same panel.

If you leave plotxy running, beware of (for instance) deleting or writing over the MS without stopping. It may work from a memory version of the MS or crash.

### 3.4.10 Example session using plotxy

The following is an example of interactive plotting and flagging using plotxy on the Jupiter 6cm continuum VLA dataset. This is extracted from the script jupiter6cm_usecase.py available in the script area.

This assumes that the MS jupiter6cm.usecase.ms is on disk with flagautocorr already run.

**BETA ALERT:** Exact syntax may be slightly different in your version as the Beta Release progress.
default('plotxy')

vis = 'jupiter6cm.usecase.ms'

# The fields we are interested in: 1331+305, JUPITER, 0137+331
selectdata = True

# First we do the primary calibrator
field = '1331+305'

# Plot only the RR and LL for now
correlation = 'RR LL'

# Plot amplitude vs. uvdist
xaxis = 'uvdist'
yaxis = 'amp'
multicolor = 'both'

# The easiest thing is to iterate over antennas
iteration = 'antenna'

plotxy()

# You'll see lots of low points as you step through RR LL RL LR
# A basic clip at 0.75 for RR LL and 0.055 for RL LR will work
# If you want to do this interactively, set
iteration = ''

plotxy()

# You can also use flagdata to do this non-interactively
# (see below)

# Now look at the cross-polar products
correlation = 'RL LR'

plotxy()

#---------------------------------------------------------------
# Now do calibrator 0137+331
field = '0137+331'
correlation = 'RR LL'
xaxis = 'uvdist'
spw = ''
iteration = ''
antenna = ''

plotxy()

# You'll see a bunch of bad data along the bottom near zero amp
# Draw a box around some of it and use Locate
Looks like much of it is Antenna 9 (ID=8) in spw=1

```python
xaxis = 'time'
spw = '1'
correlation = ''
```

Note that the strings like antenna='9' first try to match the NAME which we see in listobs was the number '9' for ID=8. So be careful here (why naming antennas as numbers is bad).

```python
antenna = '9'
```

plotxy()

YES! the last 4 scans are bad. Box 'em and flag.

Go back and clean up

```python
xaxis = 'uvdist'
spw = ''
antenna = ''
correlation = 'RR LL'
```

plotxy()

Box up the bad low points (basically a clip below 0.52) and flag

Note that RL,LR are too weak to clip on.

Finally, do JUPITER

```python
field = 'JUPITER'
correlation = ''
iteration = '',
xaxis = 'time'
```

plotxy()

Here you will see that the final scan at 22:00:00 UT is bad

Draw a box around it and flag it!

Now look at what's left

```python
correlation = 'RR LL'
xaxis = 'uvdist'
spw = '1'
antenna = '',
iteration = 'antenna'
```

plotxy()

As you step through, you will see that Antenna 9 (ID=8) is often bad in this spw. If you box and do Locate (or remember from 0137+331) it's probably a bad time.
# The easiest way to kill it:

antenna = '9'
iteration = ''
xaxis = 'time'
correlation = ''

plotxy()

# Draw a box around all points in the last bad scans and flag 'em!

# Now clean up the rest
xaxis = 'uvdist'
correlation = 'RR LL'
antenna = ''
spw = ''

# You will be drawing many tiny boxes, so remember you can
# use the ESC key to get rid of the most recent box if you
# make a mistake.

plotxy()

# Note that the end result is we've flagged lots of points
# in RR and LL. We will rely upon imager to ignore the
# RL LR for points with RR LL flagged!

### 3.5 Non-Interactive Flagging using flagdata

Task **flagdata** will flag the visibility data set based on the specified data selections, most of the information coming from a run of the **listobs** task (with/without **verbose=True**). Currently you can select based on any combination of:

- antennas (**antenna**)
- baselines (**antenna**)
- spectral windows and channels (**spw**)
- correlation types (**correlation**)
- field ids or names (**field**)
- uv-ranges (**uvrange**)
- times (**timerange**) or scan numbers (**scan**)

antenna arrays (array)

and choose to flag, unflag, clip (setclip and sub-parameters), and remove the first part of each scan (setquack) and/or the autocorrelations (autocorr).

The inputs to flagdata are:

```python
# flagdata :: Flag/Clip data based on selections:
vis = '' # Name of input visibility file
mode = 'manualflag' # Mode (manualflag, quack, shadow, autoflag, summary)
autocorr = False # Flag autocorrelations
unflag = False # Unflag the data specified
clipexpr = 'ABS RR' # Expression to clip on
clipminmax = [] # Range to use for clipping
clipcolumn = 'DATA' # Data column to use for clipping
clipoutside = True # Clip outside the range, or within it
spw = '' # spectral-window/frequency/channel
field = '' # Field names or field index numbers: ''==>all, field='0~2,3C286'
selectdata = True # More data selection parameters (antenna, timerange etc)
  antenna = '' # antenna/baselines: ''==>all, antenna = '3,VA04'
timerange = '' # time range: ''==>all, timerange='09:14:0~09:54:0'
correlation = '' # Select data based on correlation
  scan = '' # scan numbers: ''==>all
  feed = '' # multi-feed numbers: Not yet implemented
  array = '' # (sub)array numbers: ''==>all
  uvrange = '' # uv range: ''==>all; uvrange = '0~100klambda', default units=meters
async = False # If true the taskname must be started using flagdata(...)
```

The default flagging mode is 'manualflag'. See §3.5.1.1 more more on this option.

The mode='summary' will print out a summary of the current state of flagging into the logger.

The mode='quack' will allow dropping of integrations from the beginning of scans. See §3.5.1.2 for details.

The mode='shadow' option will allow shadowed data to be flagged (if it has not already during filling).

**BETA ALERT:** the mode='autoflag' option is not currently supported.

### 3.5.1 Flag Antenna/Channels

The following commands give the results shown in Figure3.5
CHAPTER 3. DATA EXAMINATION AND EDITING

```python
default('plotxy')
plotxy('ngc5921.ms','channel',iteration='antenna',subplot=311)
default('flagdata')
flagdata(vis='ngc5921.ms',antenna='0',spw='0:10~15')
default plotxy
plotxy('ngc5921.ms','channel',iteration='antenna',subplot=311)
```

Figure 3.5: **flagdata**: Example showing before and after displays using a selection of one antenna and a range of channels. Note that each invocation of the flagdata task represents a cumulative selection, i.e., running `antenna='0'` will flag all data with antenna 0, while `antenna='0', spw='0:10 15'` will flag only those channels on antenna 0.

3.5.1.1 Manual flagging and clipping in flagdata

For `mode='manualflag'`, manual flagging and clipping is controlled by the sub-parameters:

```python
mode = 'manualflag' # Mode (manualflag,autoflag,summary,quack)
autocorr = False # Flag autocorrelations
unflag = False # Unflag the data specified
clipexpr = 'ABS RR' # Expression to clip on
clipminmax = [] # Range to use for clipping
clipcolumn = 'DATA' # Data column to use for clipping
clipoutside = True # Clip outside the range, or within it
```

The following commands give the results shown in Figure 3.6.

```python
plotxy('ngc5921.ms','uvdist')
flagdata(vis='ngc5921.ms',clipexpr='LL',clipminmax=[0.0,1.6],clipoutside=True)
plotxy('ngc5921.ms','uvdist')
```
### 3.5.1.2 Flagging the beginning of scans

You can use the `mode='quack'` option to drop integrations from the beginning of scans (as in the AIPS task QUACK):

```python
mode = 'quack'  # Mode (manualflag, autoflag, summary, quack)
autocorr = False # Flag autocorrelations
unflag = False  # Unflag the data specified
quackinterval = 0.0 # Quack n seconds from scan beginning
```

Note that the time is measured from the first integration in the MS for a given scan, and this is often already flagged by the online system.

For example, assuming the integration time is 3.3 seconds (e.g. for VLA), then

```python
mode = 'quack'
quackinterval = 14.0
```

will flag the first 4 integrations in every scan.

### 3.6 Browse the Data

The `browsetable` task is available for viewing data directly (and handles all CASA tables, including Measurement Sets, calibration tables, and images). This task brings up the CASA Qt `casabrowser`, which is a separate program. You can launch this from outside `casapy`.

The default inputs are:
# browsetable :: Browse a table (MS, calibration table, image)

tablename = ''  # Name of input table

Currently, its single input is the `tablename`, so an example would be:

    browsetable('ngc5921.ms')

For an MS such as this, it will come up with a browser of the MAIN table (see Fig 3.7). If you want to look at sub-tables, use the tab table keywords along the left side to bring up a panel with the sub-tables listed (Fig 3.8), then choose (left-click) a table and View:Details to bring it up (Fig 3.9). You can left-click on a cell in a table to view the contents.

![Figure 3.7: browsetable](image)

Figure 3.7: **browsetable**: The browser displays the main table within a frame. You can scroll through the data (x=columns of the MAIN table, and y=the rows) or select a specific page or row as desired. By default, 1000 rows of the table are loaded at a time, but you can step through the MS in batches.

Note that one useful feature is that you can Edit the table and its contents. Use the Edit table choice from the **Edit** menu, or click on the **Edit** button. Be careful with this, and make a backup copy of the table before editing!

Use the Close Tables and Exit option from the **Files** menu to quit the **casabrowser**.
Figure 3.8: **browsetable**: You can use the tab for **Table Keywords** to look at other tables within an MS. You can then double-click on a table to view its contents.

There are a lot of features in the **casabrowser** that are not fully documented here. Feel free to explore the capabilities such as plotting and sorting!

**BETA ALERT**: You are likely to find that the **casabrowser** needs to get a table lock before proceeding. Use the **clearstat** command to clear the lock status in this case.

### 3.7 Plotting antenna positions (**plotants**)

This task is a simple plotting interface (to the **plotxy** functionality) to produce plots of the antenna positions (taken from the **ANTENNA** sub-table of the MS).

The inputs to **plotants** are:

```python
# plotants :: Plot the antenna distribution in the local reference frame:
vis = '' # Name of input visibility file (MS)
figfile = '' # Save the plotted figure to this file
async = False #
```
3.8 MS Plotting and Editing using casaplotms

**BETA ALERT:** The casaplotms tool is an experimental standalone plotter application based on Qt. It is intended to replace plotxy and will be integrated more fully into CASA in the next release.

There is no task or toolkit interface to casaplotms from inside casapy. You can start the application outside CASA (e.g. by typing casaplotms) or from inside the shell using the OS command syntax, either !casaplotms from IPython, or os.system(‘casaplotms’) from IPython or script.

3.9 Examples of Data Display and Flagging

See the scripts provided in Appendix F for examples of data examination and flagging. In particular, we refer the interested user to the demonstrations for:

- NGC5921 (VLA HI) — a quick demo of basic CASA capabilities [F.1]
- Jupiter (VLA 6cm continuum polarimetry) — more extensive editing [F.2]
Chapter 4

Synthesis Calibration

This chapter explains how to calibrate interferometer data within the CASA task system. Calibration is the process of determining the complex correction factors that must be applied to each visibility in order to make them as close as possible to what an idealized interferometer would measure, such that when the data is imaged an accurate picture of the sky is obtained. This is not an arbitrary process, and there is a philosophy behind the CASA calibration methodology (see § 4.2.1 for more on this). For the most part, calibration in CASA using the tasks is not too different than calibration in other packages such as AIPS or Miriad, so the user should not be alarmed by cosmetic differences such as task and parameter names!

4.1 Calibration Tasks

The standard set of calibration tasks are:

- **accum** — Accumulate incremental calibration solutions into a cumulative cal table (§ 4.5.4),
- **applycal** — Apply calculated calibration solutions (§ 4.6.1),
- **bandpass** — B calibration solving; supports pre-apply of other calibrations (§ 4.4.2),
- **clearcal** — Re-initialize visibility data set calibration data (§ 4.6.3),
- **fluxscale** — Bootstrap the flux density scale from standard calibration sources (§ 4.4.4),
- **gaincal** — G calibration solving; supports pre-apply of other calibrations (§ 4.4.3),
- **listcal** — list calibration solutions (§ 4.5.2),
- **plotcal** — Plot calibration solutions (§ 4.5.1),
- **polcal** — polarization calibration (§ 4.4.5),
• **setjy** — Compute the model visibility for a specified source flux density (§ 4.3.4),
• **smoothcal** — Smooth calibration solutions derived from one or more sources (§ 4.5.3),
• **split** — Write out new MS containing calibrated data from a subset of the original MS (§ 4.7.1).

There are some development versions of calibration and utility tasks that are recently added to the Beta Release suite:

• **hanningsmooth** — apply a Hanning smoothing filter to spectral-line uv data (§ 4.7.2),
• **uvcontsub** — uv-plane continuum fitting and subtraction (§ 4.7.4),
• **uvsub** — subtract the transform of a model image from the uv data (§ 4.7.3).

These are not yet full-featured, and may have only rudimentary controls and options.

Finally, there are also more advanced and experimental calibration tasks available in this release:

• **blcal** — baseline-based gain or bandpass calibration; supports pre-apply of other calibrations (§ 4.4.6),
• **fringecal** — Experimental: baseline-based fringe-fitting calibration solving; supports pre-apply of other calibrations (§ 4.4.7),
• **uvmodelfit** — fit a component source model to the uv data (§ 4.7.5).

The following sections outline the use of these tasks in standard calibration processes.

Information on other useful tasks and parameter setting can be found in:

• **listobs** — list what is in a MS (§ 2.3),
• **plotxy** — X-Y plotting and editing (§ 3.4),
• **flagdata** — non-interactive data flagging (§ 3.5),
• **data selection** — general data selection syntax (§ 2.6).

### 4.2 The Calibration Process — Outline and Philosophy

A work-flow diagram for CASA calibration of interferometry data is shown in Figure 4.1. This should help you chart your course through the complex set of calibration steps. In the following sections, we will detail the steps themselves and explain how to run the necessary tasks and tools.

This can be broken down into a number of discrete phases:
Figure 4.1: Flow chart of synthesis calibration operations. Not shown are use of table manipulation and plotting tasks `accum`, `plotcal`, and `smoothcal` (see Figure 4.2).
• **Prior Calibration** — set up previously known calibration quantities that need to be pre-applied, such as the flux density of calibrators, antenna gain-elevation curves, and atmospheric models. Use the `setjy` task (§4.3.4), and set the `gaincurve` (§4.3.2) and `opacity` (§4.3.3) parameters in subsequent tasks;

• **Bandpass Calibration** — solve for the relative gain of the system over the frequency channels in the dataset (if needed), having pre-applied the prior calibration. Use the `bandpass` task (§4.4.2);

• **Gain Calibration** — solve for the gain variations of the system as a function of time, having pre-applied the bandpass (if needed) and prior calibration. Use the `gaincal` task (§4.4.3);

• **Polarization Calibration** — solve for any unknown polarization leakage terms. **BETA ALERT:** Polarization Calibration tasks are now available as of Beta Release Patch 1 (§4.4.5);

• **Establish Flux Density Scale** — if only some of the calibrators have known flux densities, then rescale gain solutions and derive flux densities of secondary calibrators. Use the `fluxscale` task (§4.4.4);

• **Manipulate, Accumulate, and Iterate** — if necessary, accumulate different calibration solutions (tables), smooth, and interpolate/extrapolate onto different sources, bands, and times. Use the `accum` (§4.5.4) and `smoothcal` (§4.5.3) tasks;

• **Examine Calibration** — at any point, you can (and should) use `plotcal` (§4.5.1) and/or `listcal` (§4.5.2) to look at the calibration tables that you have created;

• **Apply Calibration to the Data** — this can be forced explicitly by using the `applycal` task (§4.6.1), and can be undone using `clearcal` (§4.6.3);

• **Post-Calibration Activities** — this includes the determination and subtraction of continuum signal from line data, the splitting of data-sets into subsets (usually single-source), and other operations (such as model-fitting). Use the `uvcontsub` (§4.7.4), `split` (§4.7.1), and `uvmodelfit` (§4.7.5) tasks.

The flow chart and the above list are in a suggested order. However, the actual order in which you will carry out these operations is somewhat fluid, and will be determined by the specific data-reduction use cases you are following. For example, you may need to do an initial **Gain Calibration** on your bandpass calibrator before moving to the **Bandpass Calibration** stage. Or perhaps the polarization leakage calibration will be known from prior service observations, and can be applied as a constituent of Prior Calibration.

### 4.2.1 The Philosophy of Calibration in CASA

Calibration is not an arbitrary process, and there is a methodology that has been developed to carry out synthesis calibration and an algebra to describe the various corruptions that data might be subject to: the Hamaker-Bregman-Sault Measurement Equation (ME), described in Appendix E. The user need not worry about the details of this mathematics as the CASA software does that for
CHAPTER 4. SYNTHESIS CALIBRATION

you. Anyway, its just matrix algebra, and your familiar scalar methods of calibration (such as in AIPS) are encompassed in this more general approach.

There are a number of “physical” components to calibration in CASA:

- **data** — in the form of the Measurement Set (§2.1). The MS includes a number of columns that can hold calibrated data, model information, and weights;

- **calibration tables** — these are in the form of standard CASA tables, and hold the calibration solutions (or parameterizations thereof);

- **task parameters** — sometimes the calibration information is in the form of CASA task parameters that tell the calibration tasks to turn on or off various features, contain important values (such as flux densities), or list what should be done to the data.

At its most basic level, Calibration in CASA is the process of taking “uncalibrated” data, setting up the operation of calibration tasks using parameters, solving for new calibration tables, and then applying the calibration tables to form “calibrated” data. Iteration can occur as necessary, with the insertion of other non-calibration steps (e.g. “self-calibration” via imaging).

4.2.2 Keeping Track of Calibration Tables

The calibration tables are the currency that is exchanged between the calibration tasks. The “solver” tasks (gaincal, bandpass, blcal, fringecal) take in the MS (which may have a calibration model in the MODEL_DATA column from setjy or ft) and previous calibration tables, and will output an “incremental” calibration table (it increments the previous calibration, if any). This table can then be smoothed using smoothcal if desired.

You can accumulate the incremental calibration onto previous calibration tables with accum, which will then output a cumulative calibration table. This task will also interpolate onto a different time scale. See §4.5.4 for more on accumulation and interpolation.

Figure 4.2 graphs the flow of these tables through the sequence

\[
\text{solve} \Rightarrow \text{smooth} \Rightarrow \text{accumulate}
\]

Note that this sequence applied to separate types of tables (e.g. ‘B’, ‘G’) although tables of other types can be previous calibration input to the solver.

The final set of cumulative calibration tables is what is applied to the data using applycal. You will have to keep track of which tables are the intermediate incremental tables, and which are cumulative, and which were previous to certain steps so that they can also be previous to later steps until accumulation. This can be a confusing business, and it will help if you adopt a consistent table naming scheme (see Figure 4.2 for an example naming scheme).
CHAPTER 4. SYNTHESIS CALIBRATION

4.2.3 The Calibration of VLA data in CASA

CASA supports the calibration of VLA data that is imported from the Archive through the importvla task. See §2.2.2 for more information.

**BETA ALERT:** Data taken both before and after the Modcomp turn-off in late June 2007 will be handled automatically by importvla. You do not need to set special parameters to do so, and it will obey the scaling specified by applytsys.

You can also import VLA data in UVFITS format with the importuvfits task (§2.2.1.1). However, in this case, you must be careful during calibration in that some prior or previous calibrations (see below) may or may not have been done in AIPS and applied (or not) before export.
For example, the default settings of AIPS FILLM will apply VLA gaincurve and approximate (weather-based) atmospheric optical depth corrections when it generates the extension table CL1. If the data is exported immediately using FITTP, then this table is included in the UVFITS file. However, CASA is not able to read or use the AIPS SN or CL tables, so that prior calibration information is lost and must be applied during calibration here (i.e. using gaincurve=True and setting the opacity parameter).

On the other hand, if you apply calibration in AIPS by using the SPLIT or SPLAT tasks to apply the CL tables before exporting with FITTP, then this calibration will be in the data itself. In this case, you do not want to re-apply these calibrations when processing in CASA.

4.3 Preparing for Calibration

There are a number of “a priori” calibration quantities that may need to be applied to the data before further calibration is carried out. These include

- **system temperature correction** — turn correlation coefficient into correlated flux density (necessary for some telescopes),
- **gain curves** — antenna gain-elevation dependence,
- **atmospheric optical depth** — attenuation of the signal by the atmosphere, correcting for its elevation dependence.
- **flux density models** — establish the flux density scale using “standard” calibrator sources, with models for resolved calibrators,

These are pre-determined effects and should be applied (if known) before solving for other calibration terms. If unknown, then they will need to be solved for as one of the standard calibration types (gain or bandpass).

We now deal with these in turn.

4.3.1 System Temperature Correction

Some telescopes, including the EVLA and the VLBA, record the visibilities in the form of raw correlation coefficient with weights proportional to the number of bits correlated. The correlation coefficient is the fraction of the total signal that is correlated, and thus multiplication by the system temperature and the antenna gain (in Jy/K) will produce visibilities with units of correlated flux density. Note that the old VLA system did this initial calibration on-line, and ALMA will also provide some level of on-line calibration (TBD).

**BETA ALERT:** There is as yet no mechanism available in importvla or in the calibration tasks to use the system temperature information provided by the VLA/EVLA on-line system to calibrate EVLA or VLBA data in raw form. This includes VLA data taken after the Modcomp turn-over
in late June 2007. You may pass the data through AIPS first. You can also just forge ahead with standard calibration. The drawback to this is that short-term changes in $T_{sys}$ which are not tracked by calibrator observations or self-calibration will remain in the data.

### 4.3.2 Antenna Gain-Elevation Curve Calibration

Large antennas (such as the 25-meter antennas used in the VLA and VLBA) have a forward gain and efficiency that changes with elevation. Gain curve calibration involves compensating for the effects of elevation on the amplitude of the received signals at each antenna. Antennas are not absolutely rigid, and so their effective collecting area and net surface accuracy vary with elevation as gravity deforms the surface. This calibration is especially important at higher frequencies where the deformations represent a greater fraction of the observing wavelength. By design, this effect is usually minimized (i.e., gain maximized) for elevations between 45 and 60 degrees, with the gain decreasing at higher and lower elevations. Gain curves are most often described as 2nd- or 3rd-order polynomials in zenith angle.

Gain curve calibration has been implemented in CASA for the VLA (only), with gain curve polynomial coefficients available directly from the CASA data repository. To make gain curve corrections for VLA data, set `gaincurve=True` for any of the calibration tasks.

**BETA ALERT:** The `gaincurve` parameter must be supplied to any calibration task that allows pre-application of the prior calibration (e.g. `bandpass`, `gaincal`, `applycal`). This should be done consistently through the calibration process. In future updates we will likely move to a separate task to calibrate the gain curve.

For example, to pre-apply the gaincurve during gain calibration:

```python
gaincal('data.ms','cal.G0',gaincurve=True, solint=0.,refant=11)
```

**NOTE:** Set `gaincurve=False` if you are not using VLA data.

The gain curve will be calculated per timestamp. Upon execution of a calibration task (e.g., `gaincal`, `bandpass`, `applycal`, etc.), the gain curve data appropriate to the observing frequencies will be automatically retrieved from the data repository and applied.

**BETA ALERT:** Currently, gain-curves for VLA are built into the CASA system and this is what is applied when `gaincurve=True`. Therefore, the application of the gain-curves, if `gaincurve=True`, is allowed only if the VLA is set as the telescope of observation in the MS, otherwise an error will be generated. Set `gaincurve=False` if you are not using VLA data. A general mechanism for incorporating gaincurve information for other arrays will be made available in future releases. Also note that the VLA gain-curves are the most recent ones (that are also supplied in AIPS). Caution should be used in applying these gaincurve corrections to VLA data taken before 2001, as antenna changes were poorly tracked previous to this time. We will include gain curves for EVLA antennas when those are measured and become available.
4.3.3 Atmospheric Optical Depth Correction

The troposphere is not completely transparent. At high radio frequencies (>15 GHz), water vapor and molecular oxygen begin to have a substantial effect on radio observations. According to the physics of radiative transmission, the effect is threefold. First, radio waves from astronomical sources are absorbed (and therefore attenuated) before reaching the antenna. Second, since a good absorber is also a good emitter, significant noise-like power will be added to the overall system noise. Finally, the optical path length through the troposphere introduces a time-dependent phase error. In all cases, the effects become worse at lower elevations due to the increased air mass through which the antenna is looking. In CASA, the opacity correction described here compensates only for the first of these effects, tropospheric attenuation, using a plane-parallel approximation for the troposphere to estimate the elevation dependence.

Opacity corrections are a component of calibration type 'T'. To make opacity corrections in CASA, an estimate of the zenith opacity is required (see observatory-specific chapters for how to measure zenith opacity). This is then supplied to the `opacity` parameter in the calibration tasks.

**BETA ALERT:** The `opacity` parameter must be supplied to any calibration task that allows pre-application of the prior calibration (e.g. `bandpass`, `gaincal`, `applycal`). This should be done consistently through the calibration process. In future updates we will likely move to a separate task to calibrate the atmospheric optical depth.

For example, if the zenith optical depth is 0.1 nepers, then use the following parameters:

```
gaincal('data.ms', 'cal.G0', solint=0., refant=11, opacity=0.1)
```

The calibration task in this example will apply an elevation-dependent opacity correction (scaled to 0.1 nepers at the zenith for all antennas for this example) calculated at each scan (`solint=0`). Set `solint=-1` instead to get a solution every timestamp.

**BETA ALERT:** Currently, you can only supply a single value of `opacity`, which will then be pre-applied to whatever calibration task that you set it in. Generalizations to antenna- and time-dependent opacities, including derivation (from weather information) and solving (directly from the visibility data) capabilities, will be made available in the future.

If you do not have an externally supplied value for `opacity`, for example from a VLA tip procedure, then you should either use an average value for the telescope, or leave it at zero and hope that your gain calibration compensates (e.g. that your calibrator is at the same elevation as your target at approximately the same time. As noted above, there are no facilities yet to estimate this from the data (e.g. by plotting TANT vs. elevation).

Below, we give instructions for determining `opacity` for VLA observations where tip-curve data is available. It is beyond the scope of this cookbook to provide information for other telescopes.

### 4.3.3.1 Determining opacity corrections for VLA data

For VLA data, zenith opacity can be measured at the frequency and during the time observations are made using a VLA tipping scan in the observe file. Historical tipping data are available at:
Choose a year, and click Go to get a list of all tipping scans that have been made for that year.

If a tipping scan was made for your observation, then select the appropriate file. Go to the bottom of the page and click on the button that says Press here to continue. The results of the tipping scan will be displayed. Go to the section called ‘Overall Fit Summary’ to find the fit quality and the fitted zenith opacity in percent. If the zenith opacity is reported as 6%, then the actual zenith optical depth value is $\text{opacity}=0.060$ for $\text{gaincal}$ and other calibration tasks.

If there were no tipping scans made for your observation, then look for others made in the same band around the same time and weather conditions. If nothing is available here, then at K and Q bands you might consider using an average value (e.g. 6% in reasonable weather). See the VLA memo

for more on the atmospheric optical depth correction at the VLA, including plots of the seasonal variations.

### 4.3.4 Setting the Flux Density Scale using (setjy)

When solving for visibility-plane calibration, CASA calibration applications compare the observed DATA column with the MODEL_DATA column. The first time that an imaging or calibration task is executed for a given MS, the MODEL_DATA column is created and initialized with unit point source flux density visibilities (unpolarized) for all sources (e.g. AMP=1, phase=0°). The setjy task is then used to set the proper flux density for flux calibrators. For sources that are recognized flux calibrators (listed in Table 4.1), setjy will calculate the flux densities, Fourier transform the data and write the results to the MODEL_DATA column. For the VLA, the default source models are customarily point sources defined by the Baars or Perley-Taylor flux density scales, or point sources of unit flux density if the flux density is unknown. The MODEL_DATA column can also be filled with a model generated from an image of the source (e.g. the Fourier transform of an image generated after initial calibration of the data).

The inputs for setjy are:

```plaintext
# setjy :: Place flux density of sources in the measurement set:

vis = '' # Name of input visibility file
field = '' # Field name list or field ids list
spw = '' # Spectral window identifier (list)
modimage = '' # Model image name
fluxdensity = -1 # Specified flux density [I,Q,U,V]
standard = 'Perley-Taylor 99' # Flux density standard
```
CHAPTER 4. SYNTHESIS CALIBRATION

Table 4.1:

<table>
<thead>
<tr>
<th>3C Name</th>
<th>B1950 Name</th>
<th>J2000 Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>3C286</td>
<td>1328+307</td>
<td>1331+305</td>
</tr>
<tr>
<td>3C48</td>
<td>0134+329</td>
<td>0137+331</td>
</tr>
<tr>
<td>3C147</td>
<td>0538+498</td>
<td>0542+498</td>

<td>1409+524</td>
<td>1411+522</td>
</tr>
</tbody>
</table>

By default the `setjy` task will cycle through all fields and spectral windows, setting the flux density either to 1 Jy (unpolarized), or if the source is recognized as one of the calibrators in the above table, to the flux density (assumed unpolarized) appropriate to the observing frequency. For example, to run `setjy` on a measurement set called `data.ms`:

```
setjy(vis='data.ms')  # This will set all fields and spectral windows
```

**BETA ALERT:** At this time, all that `setjy` does is to fill the `MODEL_DATA` column of the MS with the Fourier transform of a source model. The `ft` task (§ 5.7) will do the same thing, although it does not offer the options for flux rescaling that `setjy` does. Note also that currently `setjy` will not transform a full-Stokes model image such that all polarizations are filled correct. You need to use `ft` for this.

To limit this operation to certain fields and spectral windows, use the `field` and/or `spw` parameters, which take the usual data selection strings (§ 2.6). For example, to set the flux density of the first field (all spectral windows)

```
setjy(vis='data.ms',field='0')
```

or to set the flux density of the second field in spectral window 17

```
setjy(vis='data.ms',field='1',spw='17')
```

The full-polarization flux density (I,Q,U,V) may also be explicitly provided:

```
setjy(vis='data.ms',
      field='1',spw='16',
      fluxdensity=[3.5,0.2,0.13,0.0])  # Run setjy on field id 1, spw id 17
```

**Note:** The `setjy` (or `ft`) operation is different than the antenna gain-elevation and atmospheric opacity Prior Calibrations (§ 4.3.2–4.3.3) in that it is applied to (and carried with) the MS itself, rather than via other tables or parameters to the subsequent tasks. It is more like the Tsys correction (§ 4.3.1) in this regard.
4.3.4.1 Using Calibration Models for Resolved Sources

If the flux density calibrator is resolved at the observing frequency, the point source model generated by `setjy` will not be appropriate. If available, a model image of the resolved source at the observing frequency may be used to generate the appropriate visibilities using the `modimage` parameter (or in older versions explicitly with the `ft` task). To use this, provide `modimage` with the path to the model image. Remember, if you just give the file name, it will assume that it is in the current working directory. Note also that `setjy` using a model image will only operate on that single source, thus you would run it multiple times (with different field settings) for different sources.

Otherwise, you may need to use the `uvrange` selection (§4.4.1.2) in the calibration solving tasks to exclude the baselines where the resolution effect is significant. There is not hard and fast rule for this, though you should consider this if your calibrator is shows a drop of more than 10% on the longest baselines (use `plotxy`, §3.4, to look at this). You may need to do antenna selection also, if it is heavily resolved and there are few good baselines to the outer antennas. Note that `uvrange` may also be needed to exclude the short baselines on some calibrators that have extended flux not accounted for in the model. Note: the calibrator guides for the specific telescopes usually indicate appropriate min and max for `uvrange`. For example, see the VLA Calibration Manual at:

http://www.vla.nrao.edu/astro/calib/manual/

for details on the use of standard calibrators for the VLA.

Model images for some flux density calibrators are provided with CASA:

- Red Hat Linux RPMs (RHE4, Fedora 6): located in `/usr/lib/casapy/data/nrao/VLA/CalModels`
- MAC OSX .dmg: located in `/opt/casa/data/nrao/VLA/CalModels`
- NRAO-AOC stable: `/home/casa/data/nrao/VLA/CalModels`
- NRAO-AOC daily: `/home/ballista/casa/daily/data/nrao/VLA/CalModels`

E.g., these are found in the `data/nrao/VLA/CalModels` sub-directory of the CASA installation. For example, just point to the repository copy, e.g.

```
modimage = '/usr/lib/casapy/data/nrao/VLA/CalModels/3C48_C.im'
```

or if you like, you can copy the ones you wish to use to your working directory.

The models available are:

```
3C138_C.im  3C147_C.im  3C286_C.im  3C48_C.im  
3C138_K.im  3C147_K.im  3C286_K.im  3C48_K.im  
3C138_L.im  3C286_L.im  3C48_L.im  
3C138_Q.im  3C147_Q.im  3C286_Q.im  3C48_Q.im  
3C138_U.im  3C147_U.im  3C286_U.im  3C48_U.im  
3C138_X.im  3C147_X.im  3C286_X.im  3C48_X.im  
```
These are all un-reconvolved images of AIPS CC lists, properly scaled to the Perley-Taylor 1999 flux density for the frequencies at which they were observed.

It is important that the model image not be one convolved with a finite beam; it must have units of Jy/pixel (not Jy/beam).

Note that setjy will rescale the flux in the models for known sources (e.g. those in Table 4.1) to match those it would have calculated. It will thus extrapolated the flux out of the frequency band of the model image to whatever spectral windows in the MS are specified (but will use the structure of the source in the model image).

**BETA ALERT:** The reference position in the modimage is currently used by setjy when it does the Fourier transform, thus differences from the positions for the calibrator in the MS will show up as phase gradients in the uv-plane. If your model image position is significantly different but you don’t want this to affect your calibration, then you can doctor either the image header using imhead (§ 6.2) or in the MS (using the ms tool) as appropriate. In an upcoming Beta patch we will put in a toggle to use or ignore the position of the modimage. Note that this will not affect the flux scaling (only put in erroneous model phases); in any event small position differences, such as those arising by changing epoch from B1950 to J2000 using regridimage (§ 6.9), will be inconsequential to the calibration.

This illustrates the use of uvrange for a slightly resolved calibrator:

```python
# Import the data
importvla(archivefiles='AS776_A031015.xp2', vis='ngc7538_XBAND.ms',
          freqtol=1000000.0, bandname='X')

# Flag the ACs
flagautocorr('ngc7538_XBAND.ms')

# METHOD 1: Use point source model for 3C48, plus uvrange in solve

# Use point source model for 3C48
setjy(vis='ngc7538_XBAND.ms', field='0');

# Limit 3C48 (fieldid=0) solutions to uvrange = 0-40 klambda
gaincal(vis='ngc7538_XBAND.ms', caltable='cal.G', field='0',
        solint=60.0, refant='10', selectdata=True, uvrange='0~40klambda',
        append=False, gaincurve=False, opacity=0.0)

# Append phase-calibrator’s solutions (no uvrange) to the same table
gaincal(vis='ngc7538_XBAND.ms', caltable='cal.G', field='2',
        solint=60.0, refant='10', selectdata=True, uvrange='',
        append=True, gaincurve=False, opacity=0.0)

# Fluxscale
fluxscale(vis='ngc7538_XBAND.ms', caltable='cal.Gflx',
          reference=['0137+331'], transfer=['2230+697'],
          fluxtable='cal.Gflx', append=False)
```

while the following illustrates the use of of a model:

```python
# Import the data
importvla(archivefiles='AS776_A031015.xp2', vis='ngc7538_XBAND.ms',
          freqtol=1000000.0, bandname='X')

# Flag the ACs
flagautocorr('ngc7538_XBAND.ms')

# METHOD 1: Use point source model for 3C48, plus uvrange in solve

# Use point source model for 3C48
setjy(vis='ngc7538_XBAND.ms', field='0');

# Limit 3C48 (fieldid=0) solutions to uvrange = 0-40 klambda
gaincal(vis='ngc7538_XBAND.ms', caltable='cal.G', field='0',
        solint=60.0, refant='10', selectdata=True, uvrange='0~40klambda',
        append=False, gaincurve=False, opacity=0.0)

# Append phase-calibrator’s solutions (no uvrange) to the same table
gaincal(vis='ngc7538_XBAND.ms', caltable='cal.G', field='2',
        solint=60.0, refant='10', selectdata=True, uvrange='',
        append=True, gaincurve=False, opacity=0.0)

# Fluxscale
fluxscale(vis='ngc7538_XBAND.ms', caltable='cal.Gflx',
          reference=['0137+331'], transfer=['2230+697'],
          fluxtable='cal.Gflx', append=False)
```
CHAPTER 4. SYNTHESIS CALIBRATION

# METHOD 2: use a resolved model copied from the data respository
# for 3C48, and no uvrange
# (NB: detailed freq-dep flux scaling TBD)

# Copy the model image 3C48_X.im to the working directory first!
setjy(vis='ngc7538_XBAND.ms', field='0', modimage='3C48_X.im')

# Solutions on both calibrators with no uvrange
gaincal(vis='ngc7538_XBAND.ms', caltable='cal.G2', field='0,2',
solint=60.0, refant='10',
append=False, gaincurve=False, opacity=0.0)

# Fluxscale
fluxscale(vis='ngc7538_XBAND.ms', caltable='cal.G2', reference=['0137+331'],
transfer=['2230+697'], fluxtable='cal.G2flx', append=False)

# Both methods give 2230 flux densities ~0.7 Jy, in good agreement with
# AIPS

4.3.5 Other a priori Calibrations and Corrections

Other a priori calibrations will be added to the calibrator (cb) tool in the near future. These will include antenna-position (phase) corrections, system temperature normalization (amplitude) corrections, tropospheric phase corrections derived from Water Vapor Radiometry (WVR) measurements, instrumental line-length corrections, etc. Where appropriate, solving capabilities for these effects will also be added.

4.4 Solving for Calibration — Bandpass, Gain, Polarization

These tasks actually solve for the unknown calibration parameters, placing the results in a calibration table. They take as input an MS, and a number of parameters that specify any prior calibration or previous calibration tables to pre-apply before computing the solution. These are placed in the proper sequence of the Measurement Equation automatically.

We first discuss the parameters that are in common between many of the calibration tasks. Then we describe each solver in turn.

4.4.1 Common Calibration Solver Parameters

There are a number of parameters that are in common between the calibration “solver” tasks. These also appear in some of the other calibration manipulation and application tasks.
4.4.1.1 Parameters for Specification: vis and caltable

The input measurement set and output table are controlled by the following parameters:

\[
\begin{align*}
\text{vis} & \quad = \quad '' \quad \# \quad \text{Name of input visibility file} \\
\text{caltable} & \quad = \quad '' \quad \# \quad \text{Name of output calibration table}
\end{align*}
\]

The MS name is input in \text{vis}. If it is highlighted red in the inputs (§1.3.5.4) then it does not exist, and the task will not execute. Check the name and path in this case.

The output table name is placed in \text{caltable}. Be sure to give a unique name to the output table, or be careful. If the table exists, then what happens next will depend on the task and the values of other parameters (e.g. §4.4.1.6). The task may not execute giving a warning that the table already exists, or will go ahead and overwrite the solutions in that table, or append them. Be careful.

4.4.1.2 Selection: field, spw, and selectdata

Selection is controlled by the parameters:

\[
\begin{align*}
\text{field} & \quad = \quad '' \quad \# \quad \text{field names or index of calibrators: } ''\Rightarrow\text{all} \\
\text{spw} & \quad = \quad '' \quad \# \quad \text{spectral window:channels: } ''\Rightarrow\text{all} \\
\text{selectdata} & \quad = \quad \text{False} \quad \# \quad \text{Other data selection parameters}
\end{align*}
\]

Field and spectral window selection are so often used, that we have made these standard parameters \text{field} and \text{spw} respectively.

The \text{selectdata} parameter expands as usual, uncovering other selection sub-parameters:

\[
\begin{align*}
\text{selectdata} & \quad = \quad \text{True} \quad \# \quad \text{Other data selection parameters} \\
\text{timerange} & \quad = \quad '' \quad \# \quad \text{time range: } ''\Rightarrow\text{all} \\
\text{uvrange} & \quad = \quad '' \quad \# \quad \text{uv range: } ''\Rightarrow\text{all} \\
\text{antenna} & \quad = \quad '' \quad \# \quad \text{antenna/baselines: } ''\Rightarrow\text{all} \\
\text{scan} & \quad = \quad '' \quad \# \quad \text{scan numbers: Not yet implemented} \\
\text{msselect} & \quad = \quad '' \quad \# \quad \text{Optional data selection (Specialized. but see help)}
\end{align*}
\]

Note that if \text{selectdata}=False these parameters are not used when the task is executed, even if set underneath.

The most common \text{selectdata} parameter to use is \text{uvrange}, which can be used to exclude longer baselines if the calibrator is resolved, or short baselines of the calibrator contains extended flux not accounted for in the model (e.g. §4.3.4.1).

See §2.6 for more on the selection parameters.
4.4.1.3 Prior Calibration and Correction: parang, gaincurve and opacity

These parameters control the on-the-fly application of various calibration or effect-based corrections prior to the solving process.

The parang parameter turns on the application of the antenna-based parallactic angle correction (\(P\)) in the measurement equation. This is necessary for polarization calibration and imaging, or for cases where the parallactic angles are different for geographically spaced antennas (e.g. VLBI). For dealing with only the parallel-hand corrections (e.g. RR, LL, XX, YY) for a co-located array (e.g. the VLA or ALMA), you can set parang=False and save some computational effort. Otherwise, set parang=True to apply this correction.

There are two control parameters for applying Prior Calibration:

\[
\begin{align*}
\text{gaincurve} & = \text{False} \quad \# \text{ Apply VLA antenna gain curve correction} \\
\text{opacity} & = 0.0 \quad \# \text{ Opacity correction to apply (nepers)}
\end{align*}
\]

See §4.3 for more on Prior Calibration.

4.4.1.4 Previous Calibration: gaintable, gainfield, interp and spwmap

Calibration tables that have already been determined can also be applied before solving for the new table:

\[
\begin{align*}
\text{gaintable} & = \text{''} \quad \# \text{ Prior gain calibration table(s) to apply} \\
\text{gainfield} & = \text{''} \quad \# \text{ Field selection on prior gaintable(s)} \\
\text{interp} & = \text{''} \quad \# \text{ Interpolation mode (in time) for prior gaintable(s)} \\
\text{spwmap} & = \text{[]} \quad \# \text{ Spectral window mapping for each gaintable (see help)}
\end{align*}
\]

This is controlled by the gaintable parameter, which takes a string or list of strings giving one or more calibration tables to pre-apply. For example,

\[
\text{gaintable} = ['ngc5921.bcal','ngc5921.gcal']
\]

specifies two tables, in this case bandpass and gain calibration tables respectively.

The other parameters key off gaintable, taking single values or lists, with an entry for each table in gaintable. The order is given by that in gaintable.

The gainfield parameter specifies which fields from the respective gaintable to use to apply. This is a list, with each entry a string or list of strings. The default '' for an entry means to use all in that table. For example,

\[
\begin{align*}
\text{gaintable} & = ['ngc5921.bcal','ngc5921.gcal'] \\
\text{gainfield} & = ['1331+305', ['1331+305','1445+099']] \\
\end{align*}
\]

or using indices
\texttt{gainfield = ['0', ['0','1'] ]}

to specify the field '1331+305' from the table 'ngc5921.bcal' and fields '1331+305' and '1445+099' from the second table 'ngc5921.gcal'. We could also have wildcarded the selection, e.g.

\texttt{gainfield = ['0', '*']}

taking all fields from the second table. And of course we could have used the default

\texttt{gainfield = ['0', '']}

or even

\texttt{gainfield = ['0']}

which is to take all.

The \texttt{interp} parameter chooses the interpolation scheme to be used when pre-applying the solution in the tables. This interpolation is (currently) only in time. The choices are currently \texttt{'nearest'}, \texttt{'linear'}, and \texttt{'aipslin'}:

- \texttt{'nearest'} just picks the entry nearest in time to the visibility in question;
- \texttt{'linear'} interpolation calibrates each datum with calibration phases and amplitudes linearly interpolated from neighboring time values. In the case of phase, this mode will assume that phase jumps greater than 180° between neighboring points indicate a cycle slip, and the interpolated value will follow this change in cycle accordingly;
- \texttt{'aipslin'} emulates the classic AIPS interpolation mode with linearly interpolated amplitudes and phases derived from interpolation of the complex calibration values. While this method avoids having to track cycle slips (which is unstable for solutions with very low SNR), it will yield a phase interpolation which becomes increasingly non-linear as the spanned phase difference increases. The non-linearity mimics the behavior of \texttt{interp='nearest'} as the spanned phase difference approaches 180° (the phase of the interpolated complex calibration value initially changes very slowly, then rapidly jumps to the second value at the midpoint of the interval).

If the uncalibrated phase is changing rapidly, a \texttt{'nearest'} interpolation is not desirable. Usually, \texttt{interp='linear'} is the best choice. For example,

\texttt{interp = ['nearest', 'linear']}

uses nearest “interpolation” on the first table, and linear on the second.

The \texttt{spwmap} parameter sets the spectral window combinations to form for the \texttt{gaintable(s)}. This is a list, or a list of lists, of integers giving the \texttt{spw} IDs to map. There is one list for each table in \texttt{gaintable}, with an entry for each ID in the MS. For example,
spwmap=[0,0,1,1] # apply from spw=0 to 0,1 and 1 to 2,3

for an MS with spw=0,1,2,3. For multiple gaintable, use lists of lists, e.g.

spwmap=[ [0,0,1,1], [0,1,0,1] ] # 2nd table spw=0 to 0,2 and 1 to 1,3

BETA ALERT: This scheme for mapping the pre-apply tables is not particularly elegant, particularly for spwmap. This may change in the future.

4.4.1.5 Solving: solint, combine, preavg, refant, minblperant, minsnr

The parameters controlling common aspects of the solution are:

```
solint = 'inf' # Solution interval: egs. 'inf', '60s' (see help)
combine = '' # Data axes which to combine for solve (scan, spw, and/or field)
preavg = -1.0 # Pre-averaging interval (sec) (rarely needed)
refant = '' # Reference antenna name:'=''=no explicit reference
minblperant = 4 # Minimum baselines _per antenna_ required for solve
minsnr = 0.0 # Reject solutions below this SNR: 0==>no rejection
```

The solution interval is given by solint. If given a number without a unit, this is in seconds. The special values 'inf' and -1 specify an “infinite” solution interval encompassing the entire dataset, while 'int' or zero specify a solution every integration. aYou can use time quanta in the string, e.g. solint='1m' and solint='60s' both specify solution intervals of one minute. Note that solint interacts with combine to determine whether the solutions cross scan or field boundaries.

The parameter controlling the scope of the solution is combine. For the default combine='', solutions will break at scan, field, and spw boundaries. Specification of any of these in combine will extend the solutions over the boundaries (up to the solint). For example, combine='spw' will combine spectral windows together for solving, while combine='scan' will cross scans. Thus, to do scan-based solutions (single solution for each scan), set

```
solint = 'inf'
combine = ''
```

while

```
solint = 'inf'
combine = 'scan'
```

will make a single solution for the entire dataset (for a given field and spw). You can specify multiple choices for combination:

```
combine = 'scan,spw'
```
for example.

The reference antenna is specified by the `refant` parameter. This useful to “lock” the solutions with time, effectively rotating (after solving) the phase of the gain solution for the reference antenna to be zero (the exact effect depends on the type of solution). You can also run without a reference antenna, but in this case the solutions will float with time, with a phase that rotates around with the relative weights of the antennas in the solution (its more or less like setting the weighted sum of the antenna phases to zero). It is usually prudent to select an antenna in the center of the array that is known to be particularly stable, as any gain jumps or wanders in the `refant` will be transferred to the other antenna solutions.

Although rarely needed, setting a `preavg` time will let you average data over periods shorter than the solution interval first before solving on longer timescales.

The minimum signal-to-noise ratio allowed for an acceptable solution is specified in the `minsnr` parameter. BETA ALERT: Not all calibration tasks have this parameter.

The `minblperant` parameter sets the minimum number of baselines to other antennas that must be preset for a given antenna to get a solution.

### 4.4.1.6 Action: append and solnorm

The following parameters control some things that happen after solutions are obtained:

```plaintext
solnorm = False # Normalize solution amplitudes post-solve.
append = False # Append solutions to (existing) table. False will overwrite.
```

The `solnorm` parameter toggles on the option to normalize the solution amplitudes after the solutions are obtained. The exact effect of this depends upon the type of solution. Not all tasks include this parameter.

One should be aware when using `solnorm` that if this is done in the last stage of a chain of calibration, then the part of the calibration that is “normalized” away will be lost. It is best to use this in early stages (for example in a first bandpass calibration) so that later stages (such as final gain calibration) can absorb the lost normalization scaling. It is not strictly necessary to use `solnorm=True` at all, but is sometimes helpful if you want to have a normalized bandpass for example.

The `append` parameter, if set to `True`, will append the solutions from this run to existing solutions in `caltable`. Of course, this only matters if the table already exists. If `append=False` and `caltable` exists, it will overwrite.

### 4.4.2 Spectral Bandpass Calibration (bandpass)

For channelized data, it is often desirable to solve for the gain variations in frequency as well as in time. Variation in frequency arises as a result of non-uniform filter passbands or other dispersive effects in signal transmission. It is usually the case that these frequency-dependent effects vary
on timescales much longer than the time-dependent effects handled by the gain types 'G' and 'T'. Thus, it makes sense to solve for them as a separate term: 'B', using the \texttt{bandpass} task.

The inputs to \texttt{bandpass} are:

\begin{verbatim}
# bandpass :: Calculate a bandpass solution
vis = '' # Name of input visibility file
caltable = '' # Name of output gain calibration table
field = '' # Select field using field id(s) or field name(s)
spw = '' # Select spectral window/channels
selectdata = False # Other data selection parameters
solint = 'inf' # Solution interval
combine = 'scan' # Data axes which to combine for solve (scan, spw, and/or field)
refant = '' # Reference antenna name
minblperant = 4 # Minimum baselines _per antenna_ required for solve
solnorm = False # Normalize average solution amplitudes to 1.0
bandtype = 'B' # Type of bandpass solution (B or BPOLY)
fillgaps = 0 # Fill flagged solution channels by interpolation
append = False # Append solutions to the (existing) table
gaintable = [''] # Gain calibration table(s) to apply on the fly
gainfield = [''] # Select a subset of calibrators from gaintable(s)
interp = [''] # Interpolation mode (in time) to use for each gaintable
spwmap = [] # Spectral windows combinations to form for gaintables(s)
gaincurve = False # Apply internal VLA antenna gain curve correction
opacity = 0.0 # Opacity correction to apply (nepers)
parang = False # Apply parallactic angle correction
async = False # if True run in the background, prompt is freed
\end{verbatim}

Many of these parameters are in common with the other calibration tasks and are described above in §4.4.1.

The \texttt{bandtype} parameter selects the type of solution used for the bandpass. The choices are 'B' and 'BPOLY'. The former solves for a complex gain in each channel in the selected part of the MS. See §4.4.2.2 for more on 'B'. The latter uses a polynomial as a function of channel to fit the bandpass, and expands further to reveal a number of sub-parameters See §4.4.2.3 for more on 'BPOLY'.

It is usually best to solve for the bandpass in channel data before solving for the gain as a function of time. However, if the gains of the bandpass calibrator observations are fluctuating over the timerange of those observations, then it can be helpful to first solve for the gains of that source with \texttt{gaincal}, and input these to \texttt{bandpass} via \texttt{gaintable}. See more below on this strategy.

We now describe the issue of bandpass normalization, followed by a description of the options \texttt{bandtype='B'} and \texttt{bandtype='BPOLY'}.  

### 4.4.2.1 Bandpass Normalization

The \texttt{solnorm} parameter (§4.4.1.6) deserves more explanation in the context of the bandpass. Most users are used to seeing a normalized bandpass, where the vector sum of the antenna-based channel
gains sums to unity amplitude and zero phase. The toggle `solnorm=True` allows this. However, the parts of the bandpass solution normalized away will be still left in the data, and thus you should not use `solnorm=True` if the `bandpass` calibration is the end of your calibration sequence (e.g. you have already done all the gain calibration you want to). Note that setting `solnorm=True` will NOT rescale any previous calibration tables that the user may have supplied in `gaintable`.

You can safely use `solnorm=True` if you do the bandpass first (perhaps after a throw-away initial gain calibration) as we suggest above in §4.2 as later gain calibration stages will deal with this remaining calibration term. This does have the benefit of isolating the overall (channel independent) gains to the following `gaincal` stage. It is also recommended for the case where you have multiple scans on possibly different bandpass calibrators. It may also be preferred when applying the bandpass before doing `gaincal` and then `fluxscale` (§4.4.4), as significant variation of bandpass among antennas could otherwise enter the gain solution and make (probably subtle) adjustments to the flux scale.

We finally note that `solnorm=False` at the bandpass step in the calibration chain will in the end produce the correct results. It only means that there will be a part of what we usually think of the gain calibration inside the bandpass solution, particularly if `bandpass` is run as the first step.

### 4.4.2.2 B solutions

Calibration type 'B' differs from 'G' only in that it is determined for each channel in each spectral window. It is possible to solve for it as a function of time, but it is most efficient to keep the 'B' solving timescale as long as possible, and use 'G' or 'T' for rapid frequency-independent time-scale variations.

The 'B' solutions are limited by the signal-to-noise ratio available per channel, which may be quite small. It is therefore important that the data be coherent over the time-range of the 'B' solutions. As a result, 'B' solutions are almost always preceded by an initial 'G' or 'T' solve using `gaincal` (§4.4.3). In turn, if the 'B' solution improves the frequency domain coherence significantly, a 'G' or 'T' solution following it will be better than the original.

For example, to solve for a 'B' bandpass using a single short scan on the calibrator, then

```plaintext
default('bandpass')
vis = 'n5921.ms'
caltab = 'n5921.bcal'
gaintable = '',
gainfield = '',
interp = '',
field = '0'
spw = '',
selectdata = False
gaincurve = False
opacity = 0.0
bandtype = 'B'
solint = 'inf'
```

# Calibrator 1331+305 = 3C286 (FIELD_ID 0)
# No other selection
# No gaincurve at L-band
# No troposphere
# standard time-binned B (rather than BPOLY)
# set solution interval arbitrarily long
**CHAPTER 4. SYNTHESIS CALIBRATION**

refant = '15'  # ref antenna 15 (=VLA:N2) (ID 14)

bandpass()

On the other hand, we might have a number of scans on the bandpass calibrator spread over time, but we want a single bandpass solution. In this case, we could solve for and then pre-apply an initial gain calibration, and let the bandpass solution cross scans:

```
gaintable = 'n5921.init.gcal'  # Our previously determined G table
gainfield = '0'
interp = 'linear'  # Do linear interpolation
solint = 'inf'  # One interval over dataset
combine = 'scan'  # Solution crosses scans
```

Note that we obtained a bandpass solution for all channels in the MS. If explicit channel selection is desired, for example some channels are useless and can be avoided entirely (e.g. edge channels or those dominated by Gibbs ringing), then `spw` can be set to select only these channels, e.g.

```
spw = '0:4~59'  # channels 4-59 of spw 0
```

This is not so critical for 'B' solutions as for 'BPOLY', as each channel is solved for independently, and poor solutions can be dropped.

If you have multiple time solutions, then these will be applied using whatever interpolation scheme is specified in later tasks.

The `combine` parameter (§ 4.4.1.5) can be used to combine data across spectral windows, scans, and fields.

### 4.4.2.3 BPOLY solutions

For some observations, it may be the case that the SNR per channel is insufficient to obtain a usable per-channel 'B' solution. In this case it is desirable to solve instead for a best-fit functional form for each antenna using the `bandtype='BPOLY'` solver. The 'BPOLY' solver naturally enough fits (Chebychev) polynomials to the amplitude and phase of the calibrator visibilities as a function of frequency. Unlike ordinary 'B', a single common 'BPOLY' solution will be determined for all spectral windows specified (or implicit) in the selection. As such, it is usually most meaningful to select individual spectral windows for 'BPOLY' solves, unless groups of adjacent spectral windows are known *a priori* to share a single continuous bandpass response over their combined frequency range (e.g., PdBI data).

The 'BPOLY' solver requires a number of unique sub-parameters:

```
bandtype = 'BPOLY'  # Type of bandpass solution (B or BPOLY)
degamp = 3  # Polynomial degree for BPOLY amplitude solution
degphase = 3  # Polynomial degree for BPOLY phase solution
visnorm = False  # Normalize data prior to BPOLY solution
maskcenter = 0  # Number of channels in BPOLY to avoid in center of band
maskedge = 0  # Percent of channels in BPOLY to avoid at each band edge
```
CHAPTER 4. SYNTHESIS CALIBRATION

The \texttt{degamp} and \texttt{degphase} parameters indicate the polynomial degree desired for the amplitude and phase solutions. The \texttt{maskcenter} parameter is used to indicate the number of channels in the center of the band to avoid passing to the solution (e.g., to avoid Gibbs ringing in central channels for PdBI data). The \texttt{maskedge} drops beginning and end channels. The \texttt{visnorm} parameter turns on normalization before the solution is obtained (rather than after for \texttt{solnorm}).

The \texttt{combine} parameter (§ 4.4.1.5) can be used to combine data across spectral windows, scans, and fields.

Note that \texttt{bandpass} will allow you to use multiple fields, and can determine a single solution for all specified fields using \texttt{combine='field'}. If you want to use more than one field in the solution it is prudent to use an initial \texttt{gaincal} using proper flux densities for all sources (not just 1Jy) and use this table as an input to bandpass because in general the phase towards two (widely separated) sources will not be sufficiently similar to combine them, and you want the same amplitude scale. If you do not include amplitude in the initial \texttt{gaincal}, you probably want to set \texttt{visnorm=True} also to take out the amplitude normalization change. Note also in the case of multiple fields, that the ‘BPOLY’ solution will be labeled with the field ID of the first field used in the ‘BPOLY’ solution, so if for example you point \texttt{plotcal} at the name or ID of one of the other fields used in the solution, \texttt{plotcal} does not plot.

For example, to solve for a ‘BPOLY’ (5th order in amplitude, 7th order in phase), using data from field 2, with G corrections pre-applied:

```python
bandpass(vis='data.ms',
         caltable='cal.BPOLY',
         spw='0:2~56',
         field='0',
         bandtype='BPOLY',
         degamp=5,
         degphase=7,
         gaintable='cal.G',
         refant='14')
```

4.4.3 Complex Gain Calibration (gaincal)

The fundamental calibration to be done on your interferometer data is to calibrate the antenna-based gains as a function of time in the various frequency channels and polarizations. Some of these calibrations are known beforehand (“a priori”) and others must be determined from observations of calibrators, or from observations of the target itself (“self-calibration”).

It is best to have removed a (slowly-varying) “bandpass” from the frequency channels by solving for the bandpass (see above). Thus, the \texttt{bandpass} calibration table would be input to \texttt{gaincal} via the \texttt{gaintable} parameter (see below).

The \texttt{gaincal} task has the following inputs:

```python
# gaincal :: Determine temporal gains from calibrator observations:
```

```python
# gaincal(vis='cal.BPOLY',
         gaintable='cal.G',
         field='0',
         refant='14',
         # Select field for gain calibration
         # Use the gain solutions derived previously
         # Set the reference antenna for the gain calibration
         )
```
CHAPTER 4. SYNTHESIS CALIBRATION

vis = '' # Name of input visibility file
caltab = '' # Name of output gain calibration table
field = '' # Select field using field id(s) or field name(s)
spw = '' # Select spectral window/channels
selectdata = False # Other data selection parameters
solint = 'inf' # Solution interval (see help)
combine = '' # Data axes which to combine for solve (scan, spw, and/or field)
preavg = -1.0 # Pre-averaging interval (sec)
refant = '' # Reference antenna name
minblperant = 4 # Minimum baselines _per antenna_ required for solve
minsrr = 0.0 # Reject solutions below this SNR
gaintype = 'G' # Type of gain solution (G, T, or GSPLINE)
calmode = 'ap' # Type of solution" ('ap', 'p', 'a')
append = False # Append solutions to the (existing) table
gaintable = [] # Gain calibration table(s) to apply on the fly
gainfield = [] # Select a subset of calibrators from gaintable(s)
interp = [] # Interpolation mode (in time) to use for each gaintable
spwmap = [] # Spectral windows combinations to form for gaintables(s)
gaincurve = False # Apply internal VLA antenna gain curve correction
opacity = 0.0 # Opacity correction to apply (nepers)
parang = False # Apply parallactic angle correction
async = False

Data selection is done through the standard field, spw and selectdata expandable sub-parameters (see §2.6). The bulk of the other parameters are the standard solver parameters. See §4.4.1 above for a description of these.

The gaintype parameter selects the type of gain solution to compute. The choices are 'T', 'G', and 'GSPLINE'. The 'G' and 'T' options solve for independent complex gains in each solution interval (classic AIPS style), with 'T' enforcing a single polarization-independent gain for each co-polar correlation (e.g. RR and LL, or XX and YY) and 'G' having independent gains for these. See §4.4.3.1 for a more detailed description of 'G' solutions, and §4.4.3.2 for more on 'T'. The 'GSPLINE' fits cubic splines to the gain as a function of time. See §4.4.3.3 for more on this option.

4.4.3.1 Polarization-dependent Gain (G)

Systematic time-dependent complex gain errors are almost always the dominant calibration effect, and a solution for them is almost always necessary before proceeding with any other calibration. Traditionally, this calibration type has been a catch-all for a variety of similar effects, including: the relative amplitude and phase gain for each antenna, phase and amplitude drifts in the electronics of each antenna, amplitude response as a function of elevation (gain curve), and tropospheric amplitude and phase effects. In CASA, it is possible to handle many of these effects separately, as available information and circumstances warrant, but it is still possible to solve for the net effect using calibration type G.

Generally speaking, type G can represent any per-spectral window multiplicative polarization- and time-dependent complex gain effect downstream of the polarizers. (Polarization independent effects
**CHAPTER 4. SYNTHESIS CALIBRATION**

upstream of the polarizers may also be treated with \( G \). Multi-channel data (per spectral window) will be averaged in frequency before solving (use calibration type B to solve for frequency-dependent effects within each spectral window).

To solve for \( G \) on, say, fields 1 & 2, on a 90s timescale, and apply, e.g., gain curve corrections:

\[
\begin{align*}
gaincal('data.ms', &
\text{caltable}='cal.G', \quad \text{# Write solutions to disk file 'cal.G'} \\
\text{field}='0,1', & \quad \text{# Restrict field selection} \\
\text{solint}=90.0, & \quad \text{# Solve for phase and amp on a 90s timescale} \\
\text{gaincurve}=True & \quad \text{# Note: gaincurve=False by default} \\
\text{refant}=3) & \\
\end{align*}
\]

\[
\begin{align*}
\text{plotcal('cal.G','amp')} & \quad \text{# Inspect solutions}
\end{align*}
\]

These \( G \) solution will be referenced to antenna 4. Choose a well-behaved antenna that is located near the center of the array for the reference antenna. For non-polarization datasets, reference antennae need not be specified although you can if you want. If no reference antenna is specified, an effective phase reference that is an average over the data will be calculated and used. For data that requires polarization calibration, you must choose a reference antenna that has a constant phase difference between the right and left polarizations (e.g. no phase jumps or drifts). If no reference antenna (or a poor one) is specified, the phase reference may have jumps in the R–L phase, and the resulting polarization angle response will vary during the observation, thus corrupting the polarization imaging.

To apply this solution to the calibrators and the target source (field 2, say):

\[
\begin{align*}
\text{applycal('data.ms', } &
\text{field}='0,1,2', \quad \text{# Restrict field selection (cals + src)} \\
\text{opacity}=0.0, & \quad \text{# Don’t apply opacity correction} \\
\text{gaintable}='cal.G') & \quad \text{# Apply G solutions and correct data} \\
\text{# (written to the CORRECTED_DATA column)} \\
\text{# Note: calwt=True by default} \\
\text{plotxy('data.ms',xaxis='channel',datacolum='data',subplot=211)} & \\
\text{plotxy('data.ms',xaxis='channel',datacolum='corrected',subplot=212)} & \\
\end{align*}
\]

**4.4.3.2 Polarization-independent Gain (T)**

At high frequencies, it is often the case that the most rapid time-dependent gain errors are introduced by the troposphere, and are polarization-independent. It is therefore unnecessary to solve for separate time-dependent solutions for both polarizations, as is the case for \( 'G' \). Calibration type \( 'T' \) is available to calibrate such tropospheric effects, differing from \( 'G' \) only in that a single common solution for both polarizations is determined. In cases where only one polarization is observed, type \( 'T' \) is adequate to describe the time-dependent complex multiplicative gain calibration.

In the following example, we assume we have a \( 'G' \) solution obtained on a longish timescale (longer than a few minutes, say), and we want a residual \( 'T' \) solution to track the polarization-independent variations on a very short timescale:
CHAPTER 4. SYNTHESIS CALIBRATION

```python
gaincal('data.ms',
    caltable='cal.T',
    gaintype='T',
    field='0,1',
    solint=3.0,
    gaintable='cal120.G')
```

For dual-polarization observations, it will always be necessary to obtain a 'G' solution to account for differences and drifts between the polarizations (which traverse different electronics), but solutions for rapidly varying polarization-independent effects such as those introduced by the troposphere will be optimized by using 'T'. Note that 'T' can be used in this way for self-calibration purposes, too.

### 4.4.3.3 GSPLINE solutions

At high radio frequencies, where tropospheric phase fluctuates rapidly, it is often the case that there is insufficient signal-to-noise ratio to obtain robust 'G' or 'T' solutions on timescales short enough to track the variation. In this case it is desirable to solve for a best-fit functional form for each antenna using the 'GSPLINE' solver. This fits a time-series of cubic B-splines to the phase and/or amplitude of the calibrator visibilities.

The `combine` parameter (§14.1.5) can be used to combine data across spectral windows, scans, and fields. Note that if you want to use `combine='field'`, then all fields used to obtain a 'GSPLINE' amplitude solution must have models with accurate relative flux densities. Use of incorrect relative flux densities will introduce spurious variations in the 'GSPLINE' amplitude solution.

The 'GSPLINE' solver requires a number of unique additional parameters, compared to ordinary 'G' and 'T' solving. The sub-parameters are:

```python

gaintype = 'GSPLINE'  # Type of solution (G, T, or GSPLINE)
splinetime = 3600.0   # Spline (smooth) timescale (sec), default=1 hours
npointaver = 3        # Points to average for phase wrap (okay)
phasewrap = 180       # Wrap phase when greater than this (okay)
```

The duration of each spline segment is controlled by `splinetime`. The actual splinetime will be adjusted such that an integral number of equal-length spline segments will fit within the overall range of data.

Phase splines require that cycle ambiguities be resolved prior to the fit; this operation is controlled by `npointaver` and `phasewrap`. The `npointaver` parameter controls how many contiguous points in the time-series are used to predict the cycle ambiguity of the next point in the time-series, and `phasewrap` sets the threshold phase jump (in degrees) that would indicate a cycle slip. Large values of `npointaver` improve the SNR of the cycle estimate, but tend to frustrate ambiguity detection if the phase rates are large. The `phasewrap` parameter may be adjusted to influence when cycles are detected. Generally speaking, large values (> 180°) are useful when SNR is high and phase rates are low. Smaller values for `phasewrap` can force cycle slip detection when low SNR conspires to
obscure the jump, but the algorithm becomes significantly less robust. More robust algorithms for phase-tracking are under development (including fringe-fitting).

For example, to solve for 'GSPLINE' phase and amplitudes, with splines of duration 600 seconds,

\[
\text{gaincal('data.ms',}
\text{caltable='cal.spline.ap',}
\text{gaintype='GSPLINE' \# Solve for GSPLINE}
\text{calmode='ap' \# Solve for amp & phase}
\text{field='0,1', \# Restrict data selection to calibrators}
\text{splinetime=600.) \# Set spline timescale to 10min}
\]

**BETA ALERT**: The 'GSPLINE' solutions can not yet be used in fluxscale. You should do at least some 'G' amplitude solutions to establish the flux scale, then do 'GSPLINE' in phase before or after to fix up the short timescale variations. Note that the “phase tracking” algorithm in 'GSPLINE' needs some improvement.

### 4.4.4 Establishing the Flux Density Scale (fluxscale)

The 'G' or 'T' solutions obtained from calibrators for which the flux density was unknown and assumed to be 1 Jansky are correct in a time- and antenna- relative sense, but are mis-scaled by a factor equal to the inverse of the square root of the true flux density. This scaling can be corrected by enforcing the constraint that mean gain amplitudes determined from calibrators of unknown flux density should be the same as determined from those with known flux densities. The fluxscale task exists for this purpose.

The inputs for fluxscale are:

```plaintext
# fluxscale :: Bootstrap the flux density scale from standard calibrators
vis = '' # Name of input visibility file
caltab = '' # Name of input calibration table
fluxtable = '' # Name of output, flux-scaled calibration table
reference = '' # Reference field name(s) (transfer flux scale FROM)
transfer = '' # Transfer field name(s) (transfer flux scale TO), '' -> all
append = False # Append solutions?
refspwmap = [-1] # Scale across spectral window boundaries. See help fluxscale
async = False # If true the taskname must be started using fluxscale(...)```

Before running fluxscale, one must have first run setjy for the reference sources and run a gaincal on both reference and transfer fields. After running fluxscale the output fluxtable caltable will have been scaled such that the correct scaling will be applied to the transfer sources.

For example, given a 'G' table, e.g. 'cal.G', containing solutions for a flux density calibrator (in this case '3C286') and for one or more gain calibrator sources with unknown flux densities (in this example '0234+285' and '0323+022'):

\[
\text{fluxscale(vis='data.ms',}
\text{caltable='cal.G', \# Select input table}
\]
The output table, 'cal.Gflx', contains solutions that are properly scaled for all calibrators.

Note that the assertion that the gain solutions are independent of the calibrator includes the assumption that the gain amplitudes are strictly not systematically time dependent. While synthesis antennas are designed as much as possible to achieve this goal, in practice, a number of effects conspire to frustrate it. When relevant, it is advisable to pre-apply gaincurve and opacity corrections when solving for the 'G' solutions that will be flux-scaled (see § 4.3 and § 4.4.1.3). When the 'G' solutions are essentially constant for each calibrator separately, the fluxscale operation is likely to be robust.

The fluxscale task can be executed on either 'G' or 'T' solutions, but it should only be used on one of these types if solutions exist for both and one was solved relative to the other (use fluxscale only on the first of the two).

**BETA ALERT:** The 'GSPLINE' option is not yet supported in fluxscale (see § 4.4.3.3).

If the reference and transfer fields were observed in different spectral windows, the refspwmap parameter may be used to achieve the scaling calculation across spectral window boundaries.

The refspwmap parameter functions similarly to the standard spwmap parameter (§ 4.4.1.4), and takes a list of indices indicating the spectral window mapping for the reference fields, such that refspwmap[i]=j means that reference field amplitudes from spectral window j will be used for spectral window i.

**Note:** You should be careful when you have a dataset with spectral windows with different bandwidths, and you have observed the calibrators differently in the different spw. The flux-scaling will probably be different in windows with different bandwidths.

For example,

```python
fluxscale(vis='data.ms',
caltbl='cal.G',
fluxtable='cal.Gflx',
reference='3C286',
transfer='0234+258,0323+022')
```

will use spw=0 to scale the others, while in

```python
fluxscale(vis='data.ms',
caltbl='cal.G',
fluxtable='cal.Gflx',
reference='3C286',
transfer='0234+285,0323+022',
refspwmap=[0,0,1,1])
```

the reference amplitudes from spectral window 0 will be used for spectral windows 0 and 1 and reference amplitudes from spectral window 2 will be used for spectral windows 2 and 3.
4.4.4.1 Using Resolved Calibrators

If the flux density calibrator is resolved, the assumption that it is a point source will cause solutions on outlying antennas to be biased in amplitude. In turn, the `fluxscale` step will be biased on these antennas as well. In general, it is best to use model for the calibrator, but if such a model is not available, it is important to limit the solution on the flux density calibrator to only the subset of antennas that have baselines short enough that the point-source assumption is valid. This can be done by using `antenna` and `uvrange` selection when solving for the flux density calibrator. For example, if antennas 1 through 8 are the antennas among which the baselines are short enough that the point-source assumption is valid, and we want to be sure to limit the solutions to the use of baselines shorter than 15000 wavelengths, then we can assemble properly scaled solutions for the other calibrator as follows (note: specifying both an antenna and a `uvrange` constraint prevents inclusion of antennas with only a small number of baselines within the specified `uvrange` from being included in the solution; such antennas will have poorly constrained solutions):

As an example, we first solve for gain solutions for the flux density calibrator (3C286 observed in field 0) using a subset of antennas

```plaintext
gaincal(vis='data.ms',
caltab='cal.G',
field='0',
selectdata=True,
antenna='0~7',

uvrange='0~15klambda',
solint=90)  # On 90s timescales, write solutions to table called cal.G
```

Now solve for other calibrator (0234+285 in field 1) using all antennas (implicitly) and append these solutions to the same table

```plaintext
gaincal(vis='data.ms',
caltab='cal.G',
field='1',
solint=90,
append=T)  # Set up to write to the same table
```

Finally, run `fluxscale` to adjust scaling

```plaintext
fluxscale(vis='data.ms',
caltab='cal.G',
fluxtable='cal.Gflux',
reference='3C286',
transfer='0234+285')  # Transfer scaling to 0234+285
```

The `fluxscale` calculation will be performed using only the antennas common to both fields, but the result will be applied to all antennas on the transfer field. Note that one can nominally get by only with the `uvrange` selection, but you may find that you get strange effects from some antennas only having visibilities to a subset of the baselines and thus causing problems in the solving.
4.4.5 Instrumental Polarization Calibration (D,X)

**BETA ALERT:** The `polcal` task is now available as of Beta Patch 1. It is still undergoing extensive testing, and only basic capabilities are currently provided.

The inputs to `polcal` are:

```plaintext
# polcal :: Determine instrumental polarization from calibrator observations
vis = ''  # Name of input visibility file
caltbl = ''  # Name of output gain calibration table
field = ''  # Select field using field id(s) or field name(s)
spw = ''  # Select spectral window/channels
selectdata = False  # Other data selection parameters
solint = 'inf'  # Solution interval
combine = 'scan'  # Data axes which to combine for solve (scan, spw, and/or field)
preavg = 300.0  # Pre-averaging interval (sec)
refant = ''  # Reference antenna name
minblperant = 4  # Minimum baselines _per antenna_ required for solve
minsnr = 0.0  # Reject solutions below this SNR
poltype = 'D+QU'  # Type of instrumental polarization solution (see help)
append = False  # Append solutions to the (existing) table
gaintable = ['']  # Gain calibration table(s) to apply
gainfield = ['']  # Select a subset of calibrators from gaintable(s)
interp = ['']  # Interpolation mode (in time) to use for each gaintable
spwmap = ['']  # Spectral windows combinations to form for gaintables(s)
gaincurve = False  # Apply internal VLA antenna gain curve correction
opacity = 0.0  # Opacity correction to apply (nepers)
async = False
```

The `polcal` task uses many of the standard calibration parameters as described above in §4.4.1.

The key parameter controlling `polcal` is `poltype`. The choices are:

- **'D'** — Solve for instrumental polarization (leakage D-terms), using the transform of an IQU model in `MODEL_DATA`; requires no parallactic angle coverage, but if the source polarization is non-zero, the gain calibration must have the correct R-L phase registration. (Note: this is unlikely, so just use 'D+X' to let the position angle registration float.) This will produce a calibration table of type 'D'.

- **'D+X'** — Solve for instrumental polarization D-terms and the polarization position angle correction, using the transform of an IQU model in `MODEL_DATA`; this mode requires at least 2 distinct parallactic angles to separate the net instrumental polarization and the PA. This will produce a calibration table of type 'D'. **BETA ALERT:** no table of type 'X' will be produced, so you must follow this by a run of `polcal` with `polmode='X'` (see below).

- **'D+QU'** — Solve for instrumental polarization and source $Q + iU$; requires at least 3 distinct parallactic angles to separate the net instrumental polarization from the source $Q$ and $U$. Effectively sets the polarization PA to the value if the R-L phase difference were 0°. This will produce a calibration table of type 'D'.

'X' — Solve only for the position angle correction; best to use this after getting the D-terms from one of the above modes. Requires the observation of a calibrator with known $Q + iU$ (or at least known $U/Q$). This will produce a calibration table of type 'X'.

There are channelized solution modes for the above options. For example, substitute 'Df' for 'D' in the 'D*' modes described above to get a channelized D-term solution. **BETA ALERT:** 'X' solutions are currently always frequency-independent.

**BETA ALERT:** polcal will obtain a separate D-term solution for each field supplied to it. This limitation will be relaxed in the future, enabling more sensitive solutions, as well as flexibilities like solving for 'D+X' using a single scan each of two or more position angle calibrators.

### 4.4.5.1 Heuristics and Strategies for Polarization Calibration

Fundamentally, with good ordinary gain (and bandpass, if relevant) calibration already in hand, good polarization calibration must deliver both the instrumental polarization and position angle calibration. An unpolarized source can deliver only the first of these, but does not require parallactic angle coverage. A polarized source can only deliver the position angle calibration also if its polarization is known a priori. Sources that are polarized, but with unknown polarization, must always be observed with sufficient parallactic angle coverage, where "sufficient" is determined by SNR and the details of the solving mode.

These principles are stated assuming the instrumental polarization solution is solved using the "linear approximation" where cross-terms in more than a single product of the instrumental or source polarizations are ignored in the Measurement Equation (see §E). A general non-linearized solution, with sufficient SNR, may enable some relaxation of the requirements indicated here.

For instrumental polarization calibration, there are 3 types of calibrator choice:

<table>
<thead>
<tr>
<th>Cal Polarization</th>
<th>Parallactic Angles</th>
<th>MODEL_DATA</th>
<th>polmode</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>unpolarized</td>
<td>any</td>
<td>set $Q = U = 0$</td>
<td>'D' or 'Df'</td>
<td>D-terms only</td>
</tr>
<tr>
<td>known non-zero</td>
<td>2+ scans</td>
<td>set $Q, U$</td>
<td>'D+X' or 'Df+X'</td>
<td>D-terms and PA</td>
</tr>
<tr>
<td>unknown</td>
<td>3+ scans</td>
<td>ignored</td>
<td>'D+QU' or 'Df+QU'</td>
<td>D-terms and source</td>
</tr>
</tbody>
</table>

Note that the parallactic angle ranges spanned by the scans in the modes that require this should be large enough to give good separation between the components of the solution. In practice, 60° is a good target.

Each of these solutions should be followed with a 'X' solution on a source with known polarization position angle (and correct $Q + iU$ in MODEL_DATA). **BETA ALERT:** polmode='D+X' will soon deliver this automatically.

The polcal task will solve for the 'D' or 'X' terms using the model visibilities that are in the MODEL_DATA column of the MS. Calibration of the parallel hands must have already been carried out using gaincal and/or bandpass in order to align the phases over time and frequency. This
calibration need not have been applied and can be supplied through the \texttt{gaintable} parameters, but any cal-tables to be used in \texttt{polcal} must agree (e.g. have been derived from) the data in the \texttt{DATA} column and the model visibilities in the \texttt{MODEL_DATA} column of the MS. Thus, for example, one would not use the cal-table produced by \texttt{fluxscale} as the rescaled amplitudes would no longer agree with the contents of \texttt{MODEL_DATA}.

Be careful when using resolved calibrators for polarization calibration. A particular problem is if the structure in \texttt{Q} and \texttt{U} is offset from that in \texttt{I}. Use of a point model, or a resolved model for \texttt{I} but point models for \texttt{Q} and \texttt{U}, can lead to errors in the \texttt{'X'} calibration. Use of a \texttt{uvrange} will help here. The use of a full-Stokes model with the correct polarization is the only way to ensure a correct calibration if these offsets are large.

\subsection{A Polarization Calibration Example}

In the following example, we do a standard \texttt{'D+QU'} solution on the bright source BLLac (2202+422) which has been tracked through a range in parallactic angle:

\begin{verbatim}
    default('polcal')
    vis          = 'polcal_20080224.cband.all.ms'
    caltable     = 'polcal_20080224.cband.all.pcal'
    field        = '2202+422'
    spw          = ''
    solint       = 'inf'
    combine      = 'scan'
    preavg       = 300.0
    refant       = 'VA15'
    minsnr       = 3
    poltype      = 'D+QU'
    gaintable    = 'polcal_20080224.cband.all.gcal'
    gainfield    = ['']
    polcal()
\end{verbatim}

This assumes \texttt{setjy} and \texttt{gaincal} have already been run. Note that the original gain-calibration table is used in \texttt{gaintable} so that what is in the \texttt{MODEL_DATA} column is in agreement with what is in the \texttt{gaintable}, rather than using the table resulting from \texttt{fluxscale}.

A bit later on, we need to set the R-L phase using a scan on 3C48 (0137+331):

\begin{verbatim}
    default('polcal')
    vis          = 'polcal_20080224.cband.all.ms'
    caltable     = 'polcal_20080224.cband.all.polyx'
    field        = '0137+331'
    refant       = 'VA15'
    minsnr       = 3
    poltype      = 'X'
    gaintable    = ['polcal_20080224.cband.all.gcal', 'polcal_20080224.cband.all.pcal']
    polcal()
\end{verbatim}
If, on the other hand, we had a scan on an unpolarized bright source, for example 3C84 (0319+415), we could use this to calibrate the leakages:

default('polcal')
vis = 'polcal_20080224.cband.all.ms'
caltab = 'polcal_20080224.cband.all_3c84.pcal'
field = '0319+415'
refant = 'VA15'
poltype = 'D'
gaintable = 'polcal_20080224.cband.all.gcal'
polcal()

We would then do the 'X' calibration as before (but using this D-table in gaintable).

A full processing example for continuum polarimetry can be found in §4.2.

### 4.4.6 Baseline-based Calibration (blcal)

**BETA ALERT:** The blcal task has not had extensive testing, and is included as part of our support for the ALMA and EVLA commissioning efforts.

You can use the blcal task to solve for baseline-dependent (non-closing) errors. **WARNING:** this is in general a very dangerous thing to do, since baseline-dependent errors once introduced are difficult to remove. You must be sure you have an excellent model for the source (better than the magnitude of the baseline-dependent errors).

The inputs are:

```python
# blcal :: Calculate a baseline-based calibration solution (gain or bandpass)
vis = '' # Name of input visibility file
caltab = '' # Name of output gain calibration table
field = '' # Select field using field id(s) or field name(s)
spw = '' # Select spectral window/channels
selectdata = False # Other data selection parameters
solint = 'inf' # Solution interval
combine = '' # Data axes which to combine for solve (scan, spw, and/or field)
freqdep = False # Solve for frequency dependent solutions
calmode = 'ap' # Type of solution" ('ap', 'p', 'a')
solnorm = False # Normalize average solution amplitudes to 1.0
gaintable = [''] # Gain calibration table(s) to apply on the fly
gainfield = [''] # Select a subset of calibrators from gaintable(s)
interp = [''] # Interpolation mode (in time) to use for each gaintable
spwmap = [] # Spectral windows combinations to form for gaintables(s)
gaincurve = False # Apply internal VLA antenna gain curve correction
opacity = 0.0 # Opacity correction to apply (nepers)
parang = False # Apply parallactic angle correction
async = False # If true the taskname must be started using blcal(...)
```
The `freqdep` parameter controls whether `blcal` solves for "gain" (`freqdep=True`) or "bandpass" (`freqdep=False`) style calibration.

Other parameters are the same as in other calibration tasks. These common calibration parameters are described in §4.4.1.

### 4.4.7 EXPERIMENTAL: Fringe Fitting (`fringecal`)

**BETA ALERT:** The `fringecal` task has not had extensive testing, and is included as part of our support for the ALMA commissioning effort.

The `fringecal` task provides the capability for solving for baseline-based phase, phase-delay, and delay-rate terms in the gains (G-type). This is not full antenna-based "fringe-fitting" as is commonly used in VLBI. The main use is to calibrate ALMA or EVLA commissioning data where the delays may be improperly set, and to test "fringe" solutions as a way for dealing with non-dispersive atmospheric terms.

The inputs are:

```plaintext
# fringecal :: BL-based fringe-fitting solution:
vis = ''  # Name of input visibility file (MS)
caltab = ''  # Name of output bandpass calibration table
field = ''  # Select data based on field name or index
spw = ''  # Select data based on spectral window
selectdata = False  # Activate data selection details
gaincurve = False  # Apply VLA antenna gain curve correction
opacity = 0.0  # Opacity correction to apply (nepers)
gaintable = ''  # Gain calibration solutions to apply
gainfield = ''
solint = 0.0  # Solution interval (sec)
refant = ''  # Reference antenna
async = False  # if True run in the background, prompt is freed
```

All of the `fringecal` parameters are common calibration parameters as described in §4.4.1.

**BETA ALERT:** This task has not been updated to use the new standard `solint` and `combine` syntax. Also note that `plotcal` cannot currently display 'delay' or `delayrate` solutions from `fringecal`.

### 4.5 Plotting and Manipulating Calibration Tables

At some point, the user should examine (plotting or listing) the calibration solutions. Calibration tables can also be manipulated in various ways, such as by interpolating between times (and sources), smoothing of solutions, and accumulating various separate calibrations into a single table.
CHAPTER 4. SYNTHESIS CALIBRATION

4.5.1 Plotting Calibration Solutions (plotcal)

The plotcal task is available for examining solutions of all of the basic solvable types (G, T, B, D, M, MF, K). The inputs are:

```plaintext
# plotcal :: An all-purpose plotter for calibration results:

caltab = '' # Name of input calibration table
xaxis = '' # Value to plot along x axis (time,chan,amp,phase,real,imag,snr)
yaxis = '' # Value to plot along y axis (amp,phase,real,imag,snr)
poln = '' # Polarization to plot (RL,R,L,XY,X,Y,/)  
field = '' # Field names or index: ''=all, '3C286,P1321*', '0~3'
antenna = '' # Antenna selection. E.g., antenna='3~5'
spw = '' # Spectral window: ''=all, '0,1' means spw 0 and 1
timerange = '' # Time selection ''=all
subplot = 111 # Panel number on display screen (yxn)
overplot = False # Overplot solutions on existing display
clearpanel = 'Auto' # Specify if old plots are cleared or not
iteration = '' # Iterate on antenna,time,spw,field
plotrange = [] # plot axes ranges: [xmin,xmax,ymin,ymax]
showflags = False # If true, show flags
plotsymbol = '.' # pylab plot symbol
plotcolor = 'blue' # initial plotting color
markersize = 5.0 # size of plot symbols
fontsize = 10.0 # size of label font
showgui = True # Show plot on gui
figfile = '' # ''= no plot hardcopy, otherwise supply name
```

**BETA ALERT:** Currently, plotcal needs to know the MS from which caltable was derived to get indexing information. It does this using the name stored inside the table, which does not include the full path, but assumes the MS is in the cwd. Thus if you are using a MS in a directory other than the current one, it will not find it. You need to change directories using cd in IPython (or os.chdir() inside a script) to the MS location.

The controls for the plotcal window are the same as for plotxy (see §3.4.1).

The xaxis and yaxis plot options available are:

- 'amp' — amplitude,
- 'phase' — phase,
- 'real' — the real part,
- 'imag' — the imaginary part,
- 'snr' — the signal-to-noise ratio,

of the calibration solutions that are in the caltable. The xaxis choices also include 'time' and 'channel', which will be used as the sensible defaults (if xaxis='') for gain and bandpass solutions respectively.
The `poln` parameter determines what polarization or combination of polarization is being plotted. The `poln='RL'` plots both R and L polarizations on the same plot. The respective XY options do equivalent things. The `poln='/'` option plots amplitude ratios or phase differences between whatever polarizations are in the MS (R and L, or X and Y).

The `field`, `spw`, and `antenna` selection parameters are available to obtain plots of subsets of solutions. The syntax for selection is given in §2.6.

The `subplot` parameter is particularly helpful in making multi-panel plots. The format is `subplot=yxn` where `yxn` is an integer with digit `y` representing the number of plots in the y-axis, digit `x` the number of panels along the x-axis, and digit `n` giving the location of the plot in the panel array (where `n = 1, \ldots, xy`, in order upper left to right, then down). See §3.4.3.6 for more details on this option.

The `iteration` parameter allows you to select an identifier to iterate over when producing multi-panel plots. The choices for `iteration` are: `'antenna'`, `'time'`, `'spw'`, `'field'`. For example, if per-antenna solution plots are desired, use `iteration='antenna'`. You can then use `subplot` to specify the number of plots to appear on each page. In this case, set the `n` to 1 for `subplot=yxn`. Use the Next button on the plotcal window to advance to the next set of plots. Note that if there is more than one timestamp in a 'B' table, the user will be queried to interactively advance the plot to each timestamp, or if `multiplot=True`, the antennas plots will be cycled through for each timestamp in turn. Note that `iteration` can take more than one iteration choice (as a single string containing a comma-separated list of the options).

**BETA ALERT:** the iteration order is fixed (independent of the order specified in the `iteration` string), for example:

```
iteration = 'antenna, time, field'
iteration = 'time, antenna, field'
```

will both iterate over each field (fastest) then time (next) and antenna (slowest). The order is:

```
iteration = 'antenna, time, field, spw'
```

from the slowest (outer loop) to fastest (inner loop).

The `markersize` and `fontsize` parameters are especially helpful in making the dot and label sizes appropriate for the plot being made. The screen shots in this section used this feature to make the plots more readable in the cookbook. Adjusting the `fontsize` can be tricky on multi-panel plots, as the labels can run together if too large. You can also help yourself by manually resizing the Plotter window to get better aspect ratios on the plots.

**BETA ALERT:** Unfortunately, plotcal has many of the same problems that plotxy does, as they use similar code underneath. An overhaul is underway, so stay tuned.

### 4.5.1.1 Examples for plotcal

For example, to plot amplitude or phase as a function of time for 'G' solutions (after rescaling by `fluxscale` for the NGC5921 "demo" data (see Appendix F.1),
default('plotcal')
fontsize = 14.0  # Make labels larger
markersize = 10.0  # Make dots bigger

caltab = 'ngc5921.usecase.fluxscale'
yaxis = 'amp'
subplot = 211
plotcal()

yaxis = 'phase'
subplot = 212
plotcal()

The results are shown in Figure 4.3. This makes use of the subplot option to make multi-panel displays.

Figure 4.3: Display of the amplitude (upper) and phase (lower) gain solutions for all antennas and polarizations in the ngc5921 post-fluxscale table.
Similarly, to plot amplitude or phase as a function of channel for 'B' solutions for NGC5921:

```python
default('plotcal')
fontsize = 14.0  # Make labels larger
markersize = 10.0  # Make dots bigger

caltab = 'ngc5921.usecase.bcal'
antenna = '1'
yaxis = 'amp'
subplot = 311
plotcal()

yaxis = 'phase'
subplot = 312
plotcal()

yaxis = 'snr'
subplot = 313
plotcal()
```

The results are shown in Figure 4.4. This stacks three panels with amplitude, phase, and signal-to-noise ratio. We have picked `antenna='1'` to show.

For example, to show 6 plots per page of 'B' amplitudes on a 3 × 2 grid:

```python
default('plotcal')
fontsize = 12.0  # Make labels just large enough
markersize = 10.0  # Make dots bigger

caltab = 'ngc5921.usecase.bcal'
yaxis = 'amp'
subplot = 231
iteration = 'antenna'
plotcal()
```

See Figure 4.5 for this example. This uses the `iteration` parameter.

**BETA ALERT:** Note that `plotcal` cannot currently display 'delay' or `delayrate` solutions from fringecal.

### 4.5.2 Listing calibration solutions with (listcal)

The `listcal` task will list the solutions in a specified calibration table.

The inputs are:

```python#
listcal :: List data set summary in the logger:
```
Figure 4.4: Display of the amplitude (upper), phase (middle), and signal-to-noise ratio (lower) of the bandpass 'B' solutions for \texttt{antenna='0'} and both polarizations for \texttt{ngc5921}. Note the falloff of the SNR at the band edges in the lower panel.

```python
vis = '' # Name of input visibility file (MS)
caltabell = '' # Input calibration table to list
field = '' # Select data based on field name or index
antenna = '' # Select data based on antenna name or index
spw = '' # Spectral window, channel to list
listfile = '' # Disk file to write, else to terminal
pagerows = 0 # Rows listed per page
async = False

An example listing is:

Listing CalTable: jupiter6cm.usecase.split.ms.smoothcal2 (G Jones)
```

---
**Figure 4.5:** Display of the amplitude of the bandpass 'B' solutions. Iteration over antennas was turned on using `iteration='antenna'`. The first page is shown. The user would use the **Next** button to advance to the next set of antennas.

BETA ALERT: It is likely that the format of this listing will change to better present it to the user.

4.5.3 Calibration Smoothing (smoothcal)

The smoothcal task will smooth calibration solutions (most usefully G or T) over a longer time interval to reduce noise and outliers. The inputs are:

# smoothcal :: Smooth calibration solution(s) derived from one or more sources:

vis = '' # Name of input visibility file
tablein = '' # Input calibration table
caltab = '' # Output calibration table
field = '' # Field name list
smoothtype = 'median' # Smoothing filter to use
smoothtime = 60.0 # Smoothing time (sec)
async = False # if True run in the background, prompt is freed

The smoothing will use the smoothtime and smoothtype parameters to determine the new data points which will replace the previous points on the same time sampling grid as for the tablein solutions. The currently supported smoothtype options:

- 'mean' — use the mean of the points within the window defined by smoothtime (a “boxcar” average),
- 'median' — use the median of the points within the window defined by smoothtime (most useful when many points lie in the interval).
Note that `smoothtime` defines the width of the time window that is used for the smoothing.

**BETA ALERT:** Note that `smoothcal` currently smooths by `field` and `spw`, and thus you cannot smooth solutions from different sources or bands together into one solution.

![Image of gain solutions before and after smoothing](image)

**Figure 4.6:** The ‘amp’ of gain solutions for **NGC4826** before (top) and after (bottom) smoothing with a 7200 sec `smoothtime` and `smoothtype='mean'`. Note that the first solution is in a different `spw` and on a different source, and is not smoothed together with the subsequent solutions.

An example using the `smoothcal` task to smooth an existing table:

```python
smoothcal('n4826_16apr.ms',
          tablein='n4826_16apr.gcal',
          caltable='n4826_16apr.smoothcal',
          smoothtime=7200.,
          smoothtype='mean')

# Plot up before and after tables
plotcal('n4826_16apr.gcal', '', 'amp', antenna='1', subplot=211)
```
plotcal('n4826_16apr.smoothcal','','amp',antenna='1',subplot=212)

This example uses 2 hours (7200 sec) for the smoothing time and smoothtype='mean'. The plotcal results are shown in Figure 4.6.

4.5.4 Calibration Interpolation and Accumulation (accum)

The accum task is used to interpolate calibration solutions onto a different time grid, and to accumulate incremental calibrations into a cumulative calibration table.

Its inputs are:

```plaintext
# accum :: Accumulate incremental calibration solutions

vis = '' # Name of input visibility file
tablein = '' # Input (cumulative) calibration table; use '' on first run
  accumtime = 1.0 # Timescale on which to create cumulative table

incrtable = '' # Input incremental calibration table to add
caltab = '' # Output (cumulative) calibration table
field = '' # List of field names to process from tablein.
calfiel = '' # List of field names to use from incrtable.
interp = 'linear' # Interpolation mode to use for resampling incrtable solutions
spwmap = [-1] # Spectral window combinations to apply
```

The mapping implied here is

```
tablein + incrtable => caltable
```

(mathematically the cal solutions are multiplied as complex numbers as per the Measurement Equation). The tablein is optional (see below). You must specify an incrtable and a caltable.

The tablein parameter is used to specify the existing cumulative calibration table to which an incremental table is to be applied. Initially, no such table exists, and if tablein='' then accumulate will generate one from scratch (on-the-fly), using the timescale (in seconds) specified by the sub-parameter accumtime. These nominal solutions will be unit-amplitude, zero-phase calibration, ready to be adjusted by accumulation according to the settings of other parameters. When accumtime is negative (the default), the table name specified in tablein must exist and will be used. If tablein is specified, then the entries in that table will be used.

The incrtable parameter is used to specify the incremental table that should be applied to tablein. The calibration type of incrtable sets the type assumed in the operation, so tablein (if specified) must be of the same type. If it is not, accum will exit with an error message. (Certain combinations of types and subtypes will be supported by accum in the future.)

The caltable parameter is used to specify the name of the output table to write. If un-specified (''), then tablein will be overwritten. Use this feature with care, since an error here will require building up the cumulative table from the most recent distinct version (if any).
CHAPTER 4. SYNTHESIS CALIBRATION

The field parameter specifies those field names in tablein to which the incremental solution should be applied. The solutions for other fields will be passed to caltable unaltered. If the cumulative table was created from scratch in this run of accumulate, then the solutions for these other fields will be unit-amplitude, zero-phase, as described above.

The calfield parameter is used to specify the fields to select from incrtable to use when applying to tablein. Together, use of field and calfield permit completely flexible combinations of calibration accumulation with respect to fields. Multiple runs of accum can be used to generate a single table with many combinations. In future, a 'self' mode will be enabled that will simplify the accumulation of field-specific solutions.

The spwmap parameter gives the mapping of the spectral windows in the incrtable onto those in tablein and caltable. The syntax is described in §4.1.4.

The interp parameter controls the method used for interpolation. The options are (currently): 'nearest', 'linear', and 'aipslin'. These are described in §4.1.4. For most purposes, the 'linear' option should suffice.

We now describe the two uses of accum.

4.5.4.1 Interpolation using (accum)

Calibration solutions (most notably G or T) can be interpolated onto the timestamps of the science target observations using accum.

The following example uses accum to interpolate an existing table onto a new time grid:

```python
accum(vis='n4826_16apr.ms',
     tablein='',
     accumtime=20.0,
     incrtable='n4826_16apr.gcal',
     caltable='n4826_16apr.20s.gcal',
     interp='linear',
     spwmap=[0,1,1,1,1,1])

plotcal('n4826_16apr.gcal','','phase',antenna='1',subplot=211)
plotcal('n4826_16apr.20s.gcal','','phase',antenna='1',subplot=212)
```

See Figure 4.7 for the plotcal results. The data used in this example is BIMA data (single polarization YY) where the calibrators were observed in single continuum spectral windows (spw='0,1') and the target NGC4826 was observed in 64-channel line windows (spw='2,3,4,5'). Thus, it is necessary to use spwmap=[0,1,1,1,1,1] to map the bandpass calibrator in spw='0' onto itself, and the phase calibrator in spw='1' onto the target source in spw='2,3,4,5'.

4.5.4.2 Incremental Calibration using (accum)

It is occasionally desirable to solve for and apply calibration incrementally. This is the case when a calibration table of a certain type already exists (from a previous solve), a solution of the same
CHAPTER 4. SYNTHESIS CALIBRATION

Figure 4.7: The 'phase' of gain solutions for NGC4826 before (top) and after (bottom) 'linear' interpolation onto a 20 sec accumulate grid. The first scan was 3C273 in spw='0' while the calibrator scans on 1331+305 were in spw='1'. The use of spwmap was necessary to transfer the interpolation correctly onto the NGC4826 scans.

\textit{type} and incremental \textit{relative to the first} is required, and it is not possible or convenient to recover the cumulative solution by a single solve.

Much of the time, it is, in fact, possible to recover the cumulative solution. This is because the equation describing the solution for the incremental solution (using the original solution), and that describing the solution for their product are fundamentally the same equation—the cumulative solution, if unique, must always be the same no matter what initial solution is. One circumstance where an incremental solution is necessary is the case of phase-only self-calibration relative to a full amplitude and phase calibration already obtained (from a different field).

For example, a phase-only 'G' self-calibration on a target source may be desired to tweak the full amplitude and phase 'G' calibration already obtained from a calibrator. The initial calibration (from the calibrator) contains amplitude information, and so must be carried forward, yet the
phase-only solution itself cannot (by definition) recover this information, as a full amplitude and phase self-calibration would. In this case, the initial solution must be applied while solving for the phase-only solution, then the two solutions combined to form a cumulative calibration embodying the net effect of both. In terms of the Measurement Equation, the net calibration is the product of the initial and incremental solutions.

Cumulative calibration tables also provide a means of generating carefully interpolated calibration, on variable user-defined timescales, that can be examined prior to application to the data with applycal. The solutions for different fields and/or spectral windows can be interpolated in different ways, with all solutions stored in the same table.

The only difference between incremental and cumulative calibration tables is that incremental tables are generated directly from the calibration solving tasks (gaincal, bandpass, etc), and cumulative tables are generated from other cumulative and incremental tables via accum. In all other respects (internal format, application to data with applycal, plotting with plotcal, etc.), they are the same, and therefore interchangeable. Thus, accumulate and cumulative calibration tables need only be used when circumstances require it.

The accum task represents a generalization on the classic AIPS CLCAL (see sidebox) model of cumulative calibration in that its application is not limited to accumulation of 'G' solutions. In principle, any basic calibration type can be accumulated (onto itself), as long as the result of the accumulation (matrix product) is of the same type. This is true of all the basic types, except 'D'. Accumulation is currently supported for 'B', 'G', and 'T', and, in future, 'F' (ionospheric Faraday rotation), delay-rate, and perhaps others. Accumulation of certain specialized types (e.g., 'GSPLINE', 'TOPAC', etc.) onto the basic types will be supported in the near future. The treatment of various calibration from ancillary data (e.g., system temperatures, weather data, WVR, etc.), as they become available, will also make use of accumulate to achieve the net calibration.

Note that accumulation only makes sense if treatment of a uniquely incremental solution is required (as described above), or if a careful interpolation or sampling of a solution is desired. In all other cases, re-solving for the type in question will suffice to form the net calibration of that type. For example, the product of an existing 'G' solution and an amplitude and phase 'G' self-cal (solved with the existing solution applied), is equivalent to full amplitude and phase 'G' self-cal (with no prior solution applied), as long as the timescale of this solution is at least as short as that of the existing solution.

One obvious application is to calibrate the amplitudes and phases on different timescales during self-calibration. Here is an example, using the Jupiter VLA 6m continuum imaging example (see Appendix F.2):

```python
# Put clean model into MODEL_DATA column
ft(vis='jupiter6cm.usecase.split.ms',
    model='jupiter6cm.usecase.clean1.model')
```

Other Packages:
The analog of accum in classic AIPS is the use of CLCAL to combine a series of (incremental) SN calibration tables to form successive (cumulative) CL calibration tables. AIPS SN/CL tables are the analog of 'G' tables in CASA.
# Phase only self-cal on 10s timescales
gaincal(vis='jupiter6cm.usecase.split.ms',
    caltable='jupiter6cm.usecase.phasecal1',
    gaintype='G',
    calmode='p',
    refant='6',
    solint=10.0,
    minsnr=1.0)

# Plot up solution phase and SNR
plotcal('jupiter6cm.usecase.phasecal1','','phase',antenna='1',subplot=211)
plotcal('jupiter6cm.usecase.phasecal1','','snr',antenna='1',subplot=212)

# Amplitude and phase self-cal on scans
gaincal(vis='jupiter6cm.usecase.split.ms',
    caltable='jupiter6cm.usecase.scancal1',
    gaintable='jupiter6cm.usecase.phasecal1',
    gaintype='G',
    calmode='ap',
    refant='6',
    solint='inf',
    minsnr=1.0)

# Plot up solution amp and SNR
plotcal('jupiter6cm.usecase.scancal1','','amp',antenna='1',subplot=211)
plotcal('jupiter6cm.usecase.scancal1','','snr',antenna='1',subplot=212)

# Now accumulate these - they will be on the 10s grid
accum(vis='jupiter6cm.usecase.split.ms',
    tablein='jupiter6cm.usecase.phasecal1',
    incrtable='jupiter6cm.usecase.scancal1',
    caltable='jupiter6cm.usecase.selfcal1',
    interp='linear')

# Plot this up
plotcal('jupiter6cm.usecase.selfcal1','','amp',antenna='1',subplot=211)
plotcal('jupiter6cm.usecase.selfcal1','','phase',antenna='1',subplot=212)

The final plot is shown in Figure 4.8

**BETA ALERT:** Only interpolation is offered in `accum`, no smoothing (as in `smoothcal`).

### 4.6 Application of Calibration to the Data

After the calibration solutions are computed and written to one or more calibration tables, one then needs to apply them to the data.
CHAPTER 4. SYNTHESIS CALIBRATION

Figure 4.8: The final ‘amp’ (top) and ‘phase’ (bottom) of the self-calibration gain solutions for Jupiter. An initial phase calibration on 10s solint was followed by an incremental gain solution on each scan. These were accumulated into the cumulative solution shown here.

4.6.1 Application of Calibration (applycal)

After all relevant calibration types have been determined, they must be applied to the target source(s) before splitting off to a new MS or before imaging. This is currently done by explicitly taking the data in the DATA column in the MAIN table of the MS, applying the relevant calibration tables, and creating the CORRECTED_DATA scratch column. The original DATA column is untouched.

The applycal task does this. The inputs are:

```
# applycal :: Apply calibration solution(s) to data

vis        = '' # Name of input visibility file
field      = '' # Names or indices of data fields to apply calibration ''==>all
spw        = '' # spectral window:channels: ''==>all
```
As in other tasks, setting `selectdata=True` will open up the other selection sub-parameters (see §2.6). Many of the other parameters are the common calibration parameters that are described in §4.4.1.

The single non-standard parameter is the `calwt` option to toggle the ability to scale the visibility weights by the inverse of the products of the scale factors applied to the amplitude of the antenna gains (for the pair of antennas of a given visibility). This should in almost all cases be set to its default (True). The weights should reflect the inverse noise variance of the visibility, and errors in amplitude are usually also in the weights.

For `applycal`, the list of final cumulative tables is given in `gaintable`. In this case you will have run `accum` if you have done incremental calibration for any of the types, such as ‘G’. You can also feed `gaintable` the full sets and rely on use of `gainfield`, `interp` and `spwmap` to do the correct interpolation and transfer. It is often more convenient to go through accumulation of each type with `accum` as described above (see §4.5.4.2), as this makes it easier to keep track of the sequence of incremental calibration as it is solved and applied. You can also do any required smoothing of tables using `smoothcal` (§4.5.3), as this is not yet available in `accum` or `applycal`.

If you are not doing polarization calibration or imaging, then you can set `parang=False` to make the calculations faster. If you are applying polarization calibration, or wish to make polarization images, then set `parang=True` so that the parallactic angle rotation is applied to the appropriate correlations. Currently, you must do this in `applycal` as this cannot be done on-the-fly in `clean` or `mosaic`. See §4.4.1.3 for more on `parang`.

For example, to apply the final bandpass and flux-scaled gain calibration tables solutions to the NGC5921 data:

```python
default('applycal')
vis='ngc5921.usecase.ms'
# We want to correct the calibrators using themselves
# and transfer from 1445+099 to itself and the target N5921
# Start with the fluxscale/gain and bandpass tables
gaintable=['ngc5921.usecase.fluxscale','ngc5921.usecase.bcal']
# pick the 1445+099 (field 1) out of the gaintable for transfer
# use all of the bandpass table
```
CH 4. SYNTHESIS CALIBRATION

```
gainfield = ['1','*']

# interpolation using linear for gain, nearest for bandpass
interp = ['linear','nearest']

# only one spw, do not need mapping
spwmap = []

# all channels, no other selection
spw = ''
selectdata = False

gaincurve = False
opacity = 0.0

# select the fields for 1445+099 and N5921 (fields 1 and 2)
field = '1,2'
applycal()

# Now for completeness apply 1331+305 (field 0) to itself
field = '0'
gainfield = ['0','*']
applycal()

# The CORRECTED_DATA column now contains the calibrated visibilities
```

In another example, we apply the final cumulative self-calibration of the Jupiter continuum data obtained in the example of § 4.5.4.2:

```
applycal(vis='jupiter6cm.usecase.split.ms',
         gaintable='jupiter6cm.usecase.selfcal1',
         selectdata=False)
```

Again, it is important to remember the relative nature of each calibration term. A term solved for in the presence of others is, in effect, residual to the others, and so must be used in combination with them (or new versions of them) in subsequent processing. At the same time, it is important to avoid isolating the same calibration effects in more than one term, e.g., by solving for both ‘G’ and ‘T’ separately (without applying the other), and then using them together.

It is always a good idea to examine the corrected data after calibration (using plotxy to compare the raw (‘data’) and corrected (‘corrected’) visibilities), as we describe next.

### 4.6.2 Examine the Calibrated Data

Once the source data is calibrated using applycal, you should examine the uv data and flag anything that looks bad. If you find source data that has not been flanked by calibration scans,
delete it (it will not be calibrated).

For example, to look at the calibrated Jupiter data in the last example given in the previous section:

```python
plotxy('jupiter6cm.usecase.split.ms','uvdist','amp','corrected',
       selectdata=True,correlation='RR LL',fontsize = 14.0)
```

will show the **CORRECTED_DATA** column. See Figure 4.9.

![Figure 4.9: The final 'amp' versus 'uvdist' plot of the self-calibrated Jupiter data, as shown in plotxy. The 'RR LL' correlations are selected. No outliers that need flagging are seen.](image)

See § 3.4 for a description of how to display and edit data using plotxy, and § 7.4 for use of the **viewer** to visualize and edit a Measurement Set.
4.6.3 Resetting the Applied Calibration using (clearcal)

The applycal task will set the CORRECTED_DATA column. The clearcal task will reset it to be the same as the DATA column. This may or may not be what you really want to do — nominally you will rerun applycal to get new calibration if you have changed the tables or want to apply them differently.

There is only a single input to clearcal:

```python
# clearcal :: Re-initializes calibration for an ms
vis = '' # Name of input visibility file
```

Note: clearcal also resets the MODEL_DATA column to (1,0) for all fields and spectral windows.

4.7 Other Calibration and UV-Plane Analysis Options

4.7.1 Splitting out Calibrated uv data (split)

The split task will apply calibration and output a new sub-MS containing a specified list of sources (usually a single source). The inputs are:

```python
# split :: Create a visibility subset from an existing visibility set:
vis = '' # Name of input measurement set
outputvis = '' # Name of output measurement set
datacolumn = 'corrected' # Which data column to split out
field = '' # Select field using field id(s) or field name(s)
spw = '' # Select spectral window/channels
width = 1 # Number of channels to average to form one output channel
antenna = '' # Select data based on antenna/baseline
timebin = '0s' # Value for timeaveraging
timerange = '' # Select data based on time range
scan = '' # select data based on scan numbers
uvrange = '' # select data based on uv distance range
async = False # If true the taskname must be started using split(...)
```

Usually you will run split with datacolumn='corrected' as previous operations (e.g. applycal) will have placed the calibrated data in the CORRECTED_DATA column of the MS.

For example, to split out 46 channels (5-50) from spw 1 of our NGC5921 calibrated dataset:

```python
split(vis='ngc5921.usecase.ms',
     outputvis='ngc5921.split.ms',
     field='2', # Output NGC5921 data (field 2)
     spw='0:5~50', # Select 46 chans from spw 0
datacolumn='corrected') # Take the calibrated data column
```
4.7.1.1 Averaging in \texttt{split} (EXPERIMENTAL)

\textbf{BETA ALERT:} The averaging in \texttt{split} is still problematic. In some known cases the time averaging produces incorrect results. Channel averaging seems to work, but needs more testing. User beware!

Time and channel averaging are now available using the \texttt{timebin} and \texttt{width} parameters. The \texttt{timebin} parameter give the averaging time. It takes a quantity, e.g.

\begin{verbatim}
    timebin = '30s'
\end{verbatim}

The \texttt{width} parameter defines the number of channels to average to form a given output channel. This can be specified globally for all \texttt{spw}, e.g.

\begin{verbatim}
    width = 5
\end{verbatim}

or specified per \texttt{spw}, e.g.

\begin{verbatim}
    width = [2,3]
\end{verbatim}

to average 2 channels of 1st spectral window selected and 3 in the second one.

\textbf{BETA ALERT:} The ability to average channels in both time and channel simultaneously is not yet available. Also, if you average time and channel through sequential runs of \texttt{split}, you must average in time first.

4.7.2 Hanning smoothing of uv data (\texttt{hanningsmooth})

The \texttt{hanningsmooth} task will apply Hanning smoothing to a spectral line uv data set. It will be applied to the data in the \texttt{DATA} column of the input MS and it writes the Hanning smoothed data into the \texttt{CORRECTED\_DATA} column of that same MS.

Hanning smoothing replaces the contents of channel $i$ with a weighted sum of the contents of a number of channels surrounding channel $i$. In its current form, only channels $i-1$, $i$, and $i+1$ participate, with weights 0.25, 0.50, and 0.25 respectively, but we intend to extend the kernel size in future releases. A typical use for Hanning smoothing is to remove Gibbs ringing.

The inputs are:

\begin{verbatim}
# hanningsmooth :: Hanning smooth frequency channel data
vis = 'ngc5921.split.ms'    # Name of input visibility file (MS)
async = False
\end{verbatim}

In many cases the data to be smoothed are in the \texttt{CORRECTED\_DATA} column of the MS; in that case, run \texttt{split} first to copy the contents of the \texttt{CORRECTED\_DATA} column of the input MS to the \texttt{DATA} column of the output MS. Then run \texttt{hanningsmooth} on the newly created MS.
After hanning smoothing, the contents of the first and last channel of each visibility are undefined; hanningsmooth will therefore flag the first and last channel.

**BETA ALERT:** We intend to make the kernel size a user supplied parameter. In the longer term we intend to offer other varieties of spectral smoothing as well.

### 4.7.3 Model subtraction from uv data (uvsub)

The uvsub task will subtract the value in the MODEL column from that in the CORRECTED_DATA column in the input MS and store the result in that same CORRECTED_DATA column.

The reverse operation is achieved by specifying reverse = True: in that case uvsub will add the value in the MODEL column to that in the CORRECTED_DATA column in the input MS and store the result in that same CORRECTED_DATA column.

The inputs are:

```python
# uvsub :: Subtract/add model from/to the corrected visibility data.

vis = '' # Name of input visibility file (MS)
reverse = False # reverse the operation (add rather than subtract)
async = False
```

For example:

```python
uvsub('ngc5921.split.ms')
```

**BETA ALERT:** Currently, uvsub operates on the scratch columns in the MS vis. Eventually we will provide the option to handle these columns behind the scenes and to write out a new MS.

### 4.7.4 UV-Plane Continuum Subtraction (uvcontsub)

At this point, consider whether you are likely to need continuum subtraction. If there is significant continuum emission present in what is intended as a spectral line observation, continuum subtraction may be desirable. You can estimate and subtract continuum emission in the uv-plane prior to imaging or wait and subtract an estimate of it in the image-plane. Note that neither method is ideal, and the choice depends primarily upon the distribution and strength of the continuum emission. Subtraction in the uv-plane is desirable if continuum emission dominates the source, since deconvolution of the line emission will be more robust if not subject to errors in deconvolution of the brighter continuum. There is also a performance benefit since the continuum is probably the same in each channel of the observation, and it is desirable to avoid duplication of effort. However, the main drawback of subtraction in the uv-plane is that it is only strictly correct for the phase center, since without the Fourier transform, the visibilities only describe the phase center. Thus, uv-plane continuum subtraction will be increasingly poor for emission distributed further from the phase center. If the continuum emission is relatively weak, it is usually adequate to subtract it in
the image plane; this is described in the Image Analysis section of this cookbook. Here, we describe how to do continuum subtraction in the uv-plane.

The uv-plane continuum subtraction is performed by the `uvcontsub` task. First, determine which channels in your data cube do not have line emission, perhaps by forming a preliminary image as described in the next chapter. This image will also help you decide whether or not you need to come back and do uv-plane continuum subtraction at all.

The inputs to `uvcontsub` are:

```python
# uvcontsub :: Continuum fitting and subtraction in the uv plane
vis = '' # Name of input visibility file
field = '' # Select field using field id(s) or field name(s)
fitspw = '' # Spectral window/channel selection for fitting the continuum
spw = '' # Spectral window selection for subtraction/export
solint = 'int' # Continuum fit timescale
fitorder = 0 # Polynomial order for the fit
fitmode = 'subtract' # Use of continuum fit (subtract,replace,model)
splitdata = False # Split out continuum, continuum-subtracted data
async = False
```

For each baseline, and over the timescale specified in `solint`, `uvcontsub` will provide a simple linear fit to the real and imaginary parts of the (continuum-only) channels specified in `fitspw` (using the standard `spw` selection syntax), and then subtract this model from all channels specified in `spw`, or from all channels in spectral windows of `fitspw` if `spw=''`. **BETA ALERT:** The fits are currently done independently in the spectral windows specified in `fitspw`, and thus overlapping channels in different `spw` will be corrected only with the fits from their respective `fitspw`.

Usually, one would set `solint='int'` which does no averaging and fits each integration. However, if the continuum emission comes from a small region around the phase center, then you can set `solint` larger (as long as it is shorter than the timescale for changes in the visibility function of the continuum). If your scans are short enough you can also use scan averaging `solint='inf'`. Be warned, setting `solint` too large will introduce “time smearing” in the estimated continuum and thus not properly subtracting emission not at the phase center.

Running `uvcontsub` with `fitmode='subtract'` will replace the `CORRECTED_DATA` column in the MS with continuum-subtracted line data and the `MODEL_DATA` column with the continuum model. You can use `fitmode='replace'` to replace the `CORRECTED_DATA` column with the continuum model; however, it is probably better to use `fitmode='subtract'` and then use `split` to select the `MODEL_DATA` and form a dataset appropriate for forming an image of the estimated continuum. Note that a continuum image formed from this model will only be strictly correct near the phase center, for the reasons described above.

The `splitdata` parameter can be used to have `uvcontsub` write out split MS for both the continuum-subtracted data and the continuum. It will leave the input MS in the state as if `fitmode='subtract'` was used. Note that the entire channel range of the MS will be written out (not just the channels specified in `spw` that have had the subtraction), so follow up with a `split` if you want to further restrict the output channel range. If `splitdata=True`, then `uvcontsub` will make two output MS
with names `<input msname>.contsub` and `<input msname>.cont`. **BETA ALERT:** be sure to run with `fitmode='subtract'` if setting `splitdata=True`.

Note that it is currently the case that `uvcontsub` will overwrite the `CORRECTED_DATA` column. Therefore, it is desirable to first `split` the relevant corrected data into a new Measurement Set. If you run `uvcontsub` on the original dataset, you will have to re-apply the calibration as described in the previous chapter.

So, the recommended procedure is as follows:

- Finish calibration as described in the previous chapter.
- Use `split` to form a separate dataset.
- Use the `invert` or `clean` task on the `split` result to form an exploratory image that is useful for determining the line-free channels.
- Use `uvcontsub` with `mode='subtract'` to subtract the continuum from the `CORRECTED_DATA` in the MS, and write the continuum model in the `MODEL_DATA` column. Set `splitdata=True` to have it automatically split out continuum-subtracted and continuum datasets, else do this manually.
- Image the line-only emission with the `clean` task.
- If an image of the estimated continuum is desired, and you did not use `splitdata=True`, then run `split` again (on the `uvcontsub`d dataset), and select the `MODEL_DATA`; then run `clean` to image it.

For example, we perform uv-plane continuum subtraction on our NGC5921 dataset:

```python
# Want to use channels 4-6 and 50-59 for continuum
uvcontsub(vis='ngc5921.usecase.ms',
field='N5921*',
spw='',
fitspw='0:4~7;50~59' # channels 4-6 and 50-59
solint='inf', # scans are short enough
fitorder=0 # mean only
fitmode='subtract' # uv-plane subtraction
splitdata=True) # split the data for us
```

# You will see it made two new MS:
# ngc5921.usecase.ms.cont
# ngc5921.usecase.ms.contsub

### 4.7.5 UV-Plane Model Fitting (uvmodelfit)

It is often desirable to fit simple analytic source component models directly to visibility data. Such fitting has its origins in early interferometry, especially VLBI, where arrays consisted of only a few
antennas and the calibration and deconvolution problems were poorly constrained. These methods
overcame the calibration uncertainties by fitting the models to calibration-independent closure
quantities and the deconvolution problem by drastically limiting the number of free parameters
required to describe the visibilities. Today, even with larger and better calibrated arrays, it is still
desirable to use visibility model fitting in order to extract geometric properties such as the positions
and sizes of discrete components in radio sources. Fits for physically meaningful component shapes
such as disks, rings, and optically thin spheres, though idealized, enable connecting source geometry
directly to the physics of the emission regions.

Visibility model fitting is carried out by the `uvmodelfit` task. The inputs are:

```python
# uvmodelfit :: Fit a single component source model to the uv data:

vis = '' # Name of input visibility file
field = '' # field name or index
spw = '' # spectral window
selectdata = False # Activate data selection details
niter = 5 # Number of fitting iterations to execute
comptype = 'P' # Component type (P=pt source,G=ell. gauss,D=ell. disk)
sourcepar = [1, 0, 0] # Starting guess (flux,xoff,yoff,bmajaxrat,bpa)
varypar = [] # Which parameters can vary in fit
outfile = '' # Optional output component list table
async = False # if True run in the background, prompt is freed
```

**BETA ALERT:** This task currently only fits a single component.

The user specifies the number of non-linear solution iterations (`niter`), the component type (`comptype`),
an initial guess for the component parameters (`sourcepar`), and optionally, a vector of Booleans se-
lecting which component parameters should be allowed to vary (`fixpar`), and a filename in which to
store a CASA componentlist for use in other applications (`file`). Allowed `comptypes` are currently
point 'P' or Gaussian 'G'.

The function returns a vector containing the resulting parameter list. This vector can be edited at
the command line, and specified as input (`sourcepar`) for another round of fitting.

The `sourcepar` parameter is currently the only way to specify the starting parameters for the fit.
For points, there are three parameters: I (total flux density), and relative direction (RA, Dec)
offsets (in arcsec) from the observation’s phase center. For Gaussians, there are three additional
parameters: the Gaussian’s semi-major axis width (arcsec), the aspect ratio, and position angle
(degrees). It should be understood that the quality of the result is very sensitive to the starting
parameters provided by the user. If this first guess is not sufficiently close to the global $\chi^2$ mini-
mum, the algorithm will happily converge to an incorrect local minimum. In fact, the $\chi^2$ surface,
as a function of the component’s relative direction parameters, has a shape very much like the
inverse of the absolute value of the dirty image of the field. Any peak in this image (positive or
negative) corresponds to a local $\chi^2$ minimum that could conceivable capture the fit. It is the user’s
responsibility to ensure that the correct minimum does the capturing.

Currently, `uvmodelfit` relies on the likelihood that the source is very near the phase center (within
a beamwidth) and/or the user’s savvy in specifying the starting parameters. This fairly serious
constraint will soon be relieved somewhat by enabling a rudimentary form of uv-plane weighting
to increase the likelihood that the starting guess is on a slope in the correct \( \chi^2 \) valley.

Improvements in the works for visibility model fitting include:

- User-specifiable uv-plane weighting
- Additional component shapes, including elliptical disks, rings, and optically thin spheroids.
- Optional calibration pre-application
- Multiple components. The handling of more than one component depends mostly on efficient
  means of managing the list itself (not easy in command line options), which are currently
  under development.
- Combined component and calibration fitting.

Example (see Figure 4.10):

```
# Note: It’s best to channel average the data if many channels
# before running a modelfit
split('ngc5921.ms','1445+099_avg.ms',
datacolumn='corrected',field='1445*',width='63')

# Initial guess is that it’s close to the phase center
# and has a flux of 2.0 (a priori we know it’s 2.47)
uvmodelfit('1445+099_avg.ms',
  niter=5, # Do 5 iterations
  comptype='P', # P=Point source, G=Gaussian, D=Disk
  sourcepar=[2.0,.1,.1], # Source parameters for a point source
  spw='0',
  outfile='gcal.cl') # Output component list file
```

# Output looks like:
There are 19656 - 3 = 19653 degrees of freedom.
iter=0: reduced chi2=0.0418509: I=2, dir=[0.1, 0.1] arcsec
iter=1: reduced chi2=0.003382: I=2.48562, dir=[-0.020069, -0.0268826] arcsec
iter=2: reduced chi2=0.00338012: I=2.48614, dir=[0.00323428, -0.00232235] arcsec
iter=3: reduced chi2=0.00338012: I=2.48614, dir=[0.00325324, -0.00228963] arcsec
iter=4: reduced chi2=0.00338012: I=2.48614, dir=[0.00325324, -0.00228963] arcsec
iter=5: reduced chi2=0.00338012: I=2.48614, dir=[0.00325324, -0.00228963] arcsec

If data weights are arbitrarily scaled, the following formal errors
will be underestimated by at least a factor \( \sqrt{\text{reduced chi2}} \). If
the fit is systematically poor, the errors are much worse.

\[ I = 2.48614 \pm 0.0176859 \]
\[ x = 0.00325324 \pm 0.163019 \text{ arcsec} \]
\[ y = -0.00228963 \pm 0.174458 \text{ arcsec} \]

Writing componentlist to file: /home/sandrock/smyers/Testing/Patch2/N5921/gcal.cl
# Fourier transform the component list into MODEL_DATA column of the MS
ft('1445+099_avg.ms', complist='gcal.cl')

# Plot data versus uv distance
plotxy('1445+099_avg.ms', xaxis='uvdist', datacolumn='corrected')

# Specify green circles for model data (overplotted)
plotxy('1445+099_avg.ms', xaxis='uvdist', datacolumn='model',
      overplot=True, plotsymbol='go')

Figure 4.10: Use of plotxy to display corrected data (red and blue points) and uv model fit data (green circles).

4.8 Examples of Calibration

See the scripts provided in Appendix F for examples of calibration. In particular, we refer the interested user to the demonstrations for:
• NGC5921 (VLA HI) — a quick demo of basic CASA spectral line calibration [F.1]
• Jupiter (VLA 6cm continuum polarimetry) — polarization calibration [F.2]
Chapter 5

Synthesis Imaging

This chapter describes how to make and deconvolve images starting from calibrated interferometric data, possibly supplemented with single-dish data or an image made from single-dish data. This data must be available in CASA (see § 2 on importing data). See § 4 for information on calibrating synthesis data. In the following sections, the user will learn how to make various types of images from synthesis data, reconstruct images of the sky using the available deconvolution techniques, include single-dish information in the imaging process, and to prepare to use the results of imaging for improvement of the calibration process (“self-calibration”).

5.1 Imaging Tasks Overview

The current imaging and deconvolution tasks are:

- **clean** — calculate a deconvolved image with a selected clean algorithm, including mosaicing, or make a dirty image (§ 5.3)
- **feather** — combine a single dish and synthesis image in the Fourier plane (§ 5.5)
- **deconvolve** — image-plane only deconvolution based on the dirty image and beam, using one of several algorithms (§ 5.8)
- **widefield** — a prototype task to create and deconvolve a wide-field image using w-projection and/or faceting (§ 5.4)

There are also tasks that help you set up the imaging or interface imaging with calibration:

- **makemask** - create “cleanbox” deconvolution regions (§ 5.6)
The full “tool kit” that allows expert-level imaging must still be used if you do not find enough functionality within the tasks above.

Information on other useful tasks and parameter setting can be found in:

- `listobs` — list what’s in a MS (§ 2.3),
- `split` — Write out new MS containing calibrated data from a subset of the original MS (§ section:cal.split),
- data selection — general data selection syntax (§ 2.6).
- `viewer` — image display including region statistics and image cube slice and profile capabilities (§ 7)

### 5.2 Common Imaging Task Parameters

We now describe some parameters are are common to the imaging tasks. These should behave the same way in any imaging task that they are found in. These are in alphabetical order.

**BETA ALERT:** There are still a subset of data selection parameters used in the imaging tasks: `field`, `spw`, `timerange`. In a later patch, we will use the standard data selection set (§ 2.6).

#### 5.2.1 Parameter `cell`

The `cell` parameter defines the pixel size in the x and y axes for the output image. If given as floats or integers, this is the cell size in arc seconds, e.g.

```
    cell=[0.5,0.5]
```

make 0.5” pixels. You can also give the cell size in quantities, e.g.

```
    cell=['1arcmin', '1arcmin']
```

If a single value is given, then square pixels of that size are assumed.
5.2.2 Parameter field

The field parameter selects the field indexes or names to be used in imaging. Unless you are making a mosaic, this is usually a single index or name:

\[
\text{field} = '0' \quad \# \quad \text{First field (index 0)} \\
\text{field} = '1331+305' \quad \# \quad 3c286 \\
\text{field} = '*' \quad \# \quad \text{all fields in dataset}
\]

The syntax for field selection is given in §2.6.2.

5.2.3 Parameter imagename

The value of the imagename parameter is used as the root name of the output image. Depending on the particular task and the options chosen, one or more images with names built from that root will be created. For example, the clean task run with imagename='ngc5921' a series of output images will be created with the names ngc5921.clean, ngc5921.residual, ngc5921.model, etc.

If an image with that name already exists, it will in general be overwritten. Beware using names of existing images however. If the clean is run using an imagename where <imagename>.residual and <imagename>.model already exist then clean will continue starting from these (effectively restarting from the end of the previous clean). Thus, if multiple runs of clean are run consecutively with the same imagename, then the cleaning is incremental (as in the difmap package).

5.2.4 Parameter imsize

The image size in numbers of pixels on the x and y axes is set by imsize. For example,

\[
\text{imsize} = [288, 288]
\]

makes a square image 288 pixels on a side. If a single value is given, then a square image of that dimension is made. This need not be a power of two, but for optimal performance should be a “composite” number divisible only by 2 and also 3 and/or 5. Note that in the example above \(288 = 2^5 \cdot 3^2\).

**BETA ALERT:** You will be warned if you give a non-composite imsize and it will suggest the nearest appropriate value. But it will continue cleaning so you may have to abort if you want to make use of this suggestion. This restriction will be lifted in the future when we migrate to a better FFTW engine.

5.2.5 Parameter mode

The mode parameter defines how the frequency channels in the synthesis MS are mapped onto the image. The allowed values are: mfs, channel, velocity, frequency. The mode parameter is expandable, with some options uncovering a number of sub-parameters, depending upon its value.
5.2.5.1 Mode mfs

The default mode='mfs' emulates multi-frequency synthesis in that each visibility-channel datum \(k\) with baseline vector \(B_k\) at wavelength \(\lambda_k\) is gridded into the uv-plane at \(u_k = B_k/\lambda_k\). The result is a single image plane, regardless of how many channels are in the input dataset. This image plane is at the frequency given by the midpoint between the highest and lowest frequency channels in the input spw(s). Currently, there is no way to choose the center frequency of the output image plane independently.

5.2.5.2 Mode channel

If mode='channel' is chosen, then an image cube will be created. This is an expandable parameter, with dependent parameters:

- \(\text{mode} = 'channel'\) # Type of selection (mfs, channel, velocity, frequency)
- \(\text{nchan} = 1\) # Number of channels (planes) in output image
- \(\text{start} = 0\) # first input channel to use
- \(\text{width} = 1\) # Number of input channels to average
- \(\text{interpolation} = 'nearest'\) # Type of spectral interpolation of visibilities (nearest, linear, cubic)

The channelization of the resulting image is determined by the channelization in the first MS of vis of the first spw specified (the “reference spw”). The actual channels to be gridded and used in the clean are selected via the spw parameter as usual. The resulting image cube will have \(\text{nchan}\) channels spaced evenly in frequency. The first output channel will be located at the frequency of channel \(\text{start}\) in the (first) reference spw. If \(\text{width} > 1\), then input MS channels with centers within a frequency range given by \((\text{width} + 1)/2\) times the reference spw spacing will be gridded together (as in mode='mfs' above) into the channels of the output image cube. The output channel spacing is thus given by \(\text{width}\) channels in the reference spw of the MS.

The \(\text{interpolation}\) sub-parameter (§5.2.5.5) sets how channels are gridded into the image cube planes. For 'nearest', the channels in spw beyond the first are mapped into the nearest output image channel within half a channel (if any). Otherwise, the chosen interpolation scheme will be used. Image channels that lie outside the MS frequency range or have no data mapped to them will be blank in the output image, but will be in the cube.

See the example in §F.1 for using the 'channel' mode to image a spectral-line cube. In this case, we use:

\[
\begin{align*}
\text{mode} & = 'channel' \\
\text{nchan} & = 46 \\
\text{start} & = 5 \\
\text{width} & = 1
\end{align*}
\]

which will produce a 46-channel cube starting with channel 5 of the MS with the same channel width as the MS.
5.2.5.3 Mode frequency

For mode='frequency', an output image cube is created with nchan channels spaced evenly in frequency.

```python
code
mode = 'frequency'  # Type of selection (mfs, channel, velocity, frequency)
nchan = 1  # Number of channels (planes) in output image
start = '1.4GHz'  # Frequency of first image channel: e.g. '1.4GHz'
width = '10kHz'  # Image channel width in frequency units: e.g. '1.0kHz'
interpolation = 'nearest'  # Type of spectral interpolation of visibilities (nearest, linear, cubic)
```

The frequency of the first output channel is given by start and spacing by width. The sign of width determines whether the output channels ascend or descend in frequency. Output channels have a width also given by width. Data from the input MS with centers that lie within one-half an input channel overlap of the frequency range of ±width/2 centered on the output channels are gridded together. The interpolation sub-parameter (§5.2.5.5) sets how channels are gridded into the image cube planes.

Using the NGC5921 dataset as an example:

```python
code
mode = 'frequency'
nchan = 21
start = '1412.830MHz'
width = '50kHz'
```

would produce a 21-channel output cube with 50 kHz wide channels rather than the default channelization of the MS (24.4 kHz).

5.2.5.4 Mode velocity

If mode='velocity' is chosen, then an output image cube with nchan channels will be created, with channels spaced evenly in velocity. Parameters are:

```python
code
mode = 'velocity'  # Type of selection (mfs, channel, velocity, frequency)
nchan = 1  # Number of channels (planes) in output image
start = '0.0km/s'  # Velocity of first image channel: e.g. '0.0km/s'
width = '1km/s'  # Image channel width in velocity units: e.g. '-1.0km/s'
interpolation = 'nearest'  # Type of spectral interpolation of visibilities (nearest, linear, cubic)
```

The velocity of the first output channel is given by start and spacing by width. Note that the velocity frame is given by the rest frequency in the MS header, which can be overridden by the restfreq parameter. Averaging is as in mode='frequency'. The interpolation sub-parameter (§5.2.5.5) sets how channels are gridded into the image cube planes.

Again, using the NGC5921 dataset as an example:
mode = 'velocity'
nchan = 21
start = '1383.0km/s'
width = '10km/s'

Note that in this case the velocity axis runs forward, as opposed to the default channelization for 'channel' or 'frequency'.

**BETA ALERT:** Note that the velocities are expressed in the LSRK frame. This is not currently selectable, but in the future will be through restfreq (§5.2.7).

### 5.2.5.5 Sub-parameter interpolation

The interpolation sub-parameter controls how spectral channels in the MS are gridded into the output image cube. This is available in all modes except 'mfs'. The options are: 'nearest', 'linear', 'cubic'.

For 'nearest', the channels in spw beyond the first are mapped into the nearest output image channel within half a channel (if any).

For 'linear', the channels are gridded into the planes using weights given by a linear function of the frequency of the MS channel versus the plane. Each input channel will be mapped to 1 or 2 output planes. For most users, this is the best choice.

For 'cubic', the channels are gridded using a cubic interpolation function.

### 5.2.6 Parameter phasecenter

The phasecenter parameter indicates which of the field IDs should be used to define the phase center of the mosaic image, or what that phase center is in RA and Dec. The default action is to use the first one given in the field list.

For example:

```plaintext
phasecenter='5' # field 5 in multi-src ms
phasecenter='J2000 19h30m00 -40d00m00' # specify position
```

Note that the format for angles prefers to use hm for RA/time units and dm for Dec/Angle units as separators. The colon :: separator is interpreted as RA/time even if its used for the Dec, so be careful not to copy/paste from other sources.

### 5.2.7 Parameter restfreq

The value of the *restfreq* parameter, if set, will over-ride the rest frequency in the header of the first input MS to define the velocity frame of the output image.
**BETA ALERT:** The `restfreq` parameter takes the options of transitions and frequencies as in the corresponding `plotxy` parameter (§3.4.7), but does not currently expand to allow frame information (is hardwired into LSRK).

For example:

```plaintext
restfreq='115.2712GHz',
```

will set the rest frequency to that of the CO 1-0 line.

**BETA ALERT:** Setting `restfreq` explicitly here in `clean` is good practice, and may be necessary if your MS has been concatenated from different files for different spectral windows (§2.5).

### 5.2.8 Parameter `spw`

The `spw` parameter selects the spectral windows that will be used to form the image, and possibly a subset of channels within these windows.

The `spw` parameter is a string with an integer, list of integers, or a range, e.g.

```plaintext
spw = '1'       # select spw 1
spw = '0,1,2,3' # select spw 0,1,2,3
spw = '0~3'     # same thing using ranges
```

You can select channels in the same string with a : separator, for example

```plaintext
spw = '1:10~30' # select channels 10-30 of spw 1
spw = '0:55,3:5;6;7' # chans 5-55 of spw 0 and 5,6,7 of spw 3
```

This uses the standard syntax for `spw` selection is given in §2.6.3. See that section for more options.

Note that the order in which multiple `spw`s are given is important for `mode = 'channel'`, as this defines the origin for the channelization of the resulting image.

### 5.2.9 Parameter `stokes`

The `stokes` parameter specifies the Stokes parameters for the resulting images. Note that forming Stokes Q and U images requires the presence of cross-hand polarizations (e.g. RL and LR for circularly polarized systems such as the VLA) in the data. Stokes V requires both parallel hands (RR and LL) for circularly polarized systems or the cross-hands (XY and YX) for linearly polarized systems such as ALMA and ATCA.

This parameter is specified as a string of up to four letters (IQUV). For example,

```plaintext
stokes = 'I'                  # Intensity only
stokes = 'IQU'                # Intensity and linear polarization
stokes = 'IV'                 # Intensity and circular polarization
stokes = 'IQUV'               # All Stokes imaging
```
CHAPTER 5. SYNTHESIS IMAGING

are common choices. The output image will have planes (along the "polarization axis") corresponding to the chosen Stokes parameters.

If as input to deconvolution tasks such as clean, the stokes parameter includes polarization planes other than I, then choosing psfmode='hogbom' (§5.3.1.2) or psfmode='clarkstokes' (§5.3.1.3) will clean (search for components) each plane sequentially, while psfmode='clark' (§5.3.1.1) will deconvolve jointly.

5.2.10 Parameter uvtaper

This controls the radial weighting of visibilities in the uv-plane (see §5.2.11 below) through the multiplication of the visibilities by the Fourier transform of an elliptical Gaussian. This is itself a Gaussian, and thus the visibilities are "tapered" with weights decreasing as a function of uv-radius.

The uvtaper parameter expands the menu upon setting uvtaper=True to reveal the following sub-parameters:

uvtaper = True # Apply additional uv tapering of visibilities.
outertaper = [] # uv-taper on outer baselines in uv-plane
innertaper = [] # uv-taper in center of uv-plane (not implemented)

The sub-parameters specify the size and optionally shape and orientation of this Gaussian in the uv-plane or optionally the sky plane. The outertaper refers to a Gaussian centered on the origin of the uv-plane.

Some examples:

outertaper=[] # no outer taper applied
outertaper=['5klambda'] # circular uv taper FWHM=5 kilo-lambda
outertaper=['5klambda','3klambda','45.0deg'] # elliptical Gaussian
outertaper=['10arcsec'] # on-sky FWHM 10"
outertaper=['300.0'] # 300m in aperture plane

Note that if no units are given on the taper, then the default units are assumed to be meters in aperture plane.

BETA ALERT: The innertaper option is not yet implemented.

5.2.11 Parameter weighting

In order to image your data, we must have a map from the visibilities to the image. Part of that map, which is effectively a convolution, is the weights by which each visibility is multiplied before gridding. The first factor in the weighting is the "noise" in that visibility, represented by the data weights in the MS (which is calibrated along with

Inside the Toolkit:
The im.weight method has more weighting options than available in the imaging tasks. See the User Reference Manual for more information on imaging weights.
CHAPTER 5. SYNTHESIS IMAGING

5.2.11.1 'natural' weighting

For weighting='natural', visibilities are weighted only by the data weights, which are calculated during filling and calibration and should be equal to the inverse noise variance on that visibility. Imaging weight \( w_i \) of sample \( i \) is given by

\[
\frac{w_i}{\sigma_i} = \frac{1}{\sigma_i^2}
\]

where the data weight \( \sigma_i \) is determined from the rms noise on visibility \( i \).

5.2.11.2 'uniform' weighting

For weighting='uniform', visibilities are weighted only by the data weights, which are calculated during filling and calibration and should be equal to the inverse noise variance on that visibility. Imaging weight \( w_i \) of sample \( i \) is given by

\[
\frac{w_i}{\sigma_i} = \frac{1}{\sigma_i^2}
\]

For uniform weighting, we first grid the inverse variance \( \sigma_i^2 \) for all selected data onto a grid with uv cell size given by \( 2/FOV \) where FOV is the specified field of view (defaults to the image field of view). This forms the gridded weights \( W_k \). The weight of the \( i \)-th sample is then:

\[
w_i = \frac{\omega_i}{W_k}
\]

where the data weight \( \omega_i \) is determined from \( \sigma_i \) in the same way as for 'natural' weighting.
5.2.11.3 'superuniform' weighting

The `weighting = 'superuniform'` mode is similar to the `uniform` weighting mode but there is now an additional `npixels` sub-parameter that specifies a change to the number of cells on a side (with respect to uniform weighting) to define a uv-plane patch for the weighting renormalization. If `npixels=0` you get uniform weighting.

5.2.11.4 'radial' weighting

The `weighting = 'radial'` mode is a seldom-used option that increases the weight by the radius in the uv-plane, ie.

\[ w_i = \omega_i \cdot \sqrt{u_i^2 + v_i^2}. \] (5.3)

Technically, I would call that an inverse uv-taper since it depends on uv-coordinates and not on the data per-se. Its effect is to reduce the rms sidelobes for an east-west synthesis array. This option has limited utility.

5.2.11.5 'briggs' weighting

The `weighting = 'briggs'` mode is an implementation of the flexible weighting scheme developed by Dan Briggs in his PhD thesis. See:

http://www.aoc.nrao.edu/dissertations/dbriggs/

This choice brings up the sub-parameters:

- `weighting = 'briggs'` # Weighting to apply to visibilities
- `robust = 0.0` # Briggs robustness parameter
- `npixels = 0` # number of pixels to determine uv-cell size 0=> field of view

The actual weighting scheme used is:

\[ w_i = \frac{\omega_i}{1 + W_k f^2} \] (5.4)

where \( W_k \) is defined as in uniform and superuniform weighting, and

\[ f^2 = \frac{(5 \times 10^{-R})^2}{\sum_k W_k^2 \sum_i \omega_i} \] (5.5)

and \( R \) is the robust parameter.

The key parameter is the `robust` parameter, which sets \( R \) in the Briggs equations. The scaling of \( R \) is such that \( R = 0 \) gives a good trade-off between resolution and sensitivity. The `robust` \( R \) takes value between \(-2.0\) (close to uniform weighting) to 2.0 (close to natural).

Superuniform weighting can be combined with Briggs weighting using the `npixels` sub-parameter. This works as in 'superuniform' weighting (§5.2.11.3).
5.2.11.6 ‘briggsabs’ weighting

For `weighting='briggsabs'`, a slightly different Briggs weighting is used, with

\[
\omega_i = \frac{\omega_i}{W_k R^2 + 2\sigma^2_R}
\]

where \( R \) is the robust parameter and \( \sigma_R \) is the noise parameter.

This choice brings up the sub-parameters:

```python
weighting = 'briggsabs' # Weighting to apply to visibilities
robust = 0.0 # Briggs robustness parameter
noise = '0.0Jy' # noise parameter for briggs weighting when rmode='abs'
npixels = 0 # number of pixels to determine uv-cell size 0=> field of view
```

Otherwise, this works as `weighting='briggs'` above (§5.2.11.5).

5.2.12 Parameter `vis`

The value of the `vis` parameter is either the name of a single MS, or a list of strings containing the names of multiple MSs, that should be processed to produce the image. The MS referred to by the first name in the list (if more than one) is used to determine properties of the image such as channelization and rest frequency.

For example,

```python
vis = 'ngc5921.ms'
```

set a single input MS, while

```python
vis = ['ngc5921_day1.ms', 'ngc5921_day2.ms', 'ngc5921_day3.ms']
```

points to three separate measurement sets that will be gridded together to form the image. This means that you do not have to concatenate datasets, for example from different configurations, before imaging.

5.2.13 Primary beams in imaging

The CASA imaging task and tools use primary beams based on models for each observatory’s antenna types. In addition to different antenna diameters, different functions may be used.

The voltage patterns are based on the following antenna primary beams, based on the `TELESCOPE_NAME` keyword in the `OBSERVATION` table:
CHAPTER 5. SYNTHESIS IMAGING

VLA — Airy disk fitted to measurement. Note that a R/L beam squint is also included with feed dependent angle;

ALMA — Airy disk for 12m dish with a blockage of 1m;

ATA — Airy disk for 6m dish;

ATCA — polynomial fitted to measurement of main lobe;

BIMA, HATCREEK — Gaussian with halfwidth of $\lambda/2D$;

CARMA — Airy patterns for the BIMA or OVRO dish sizes as appropriate;

GBT — polynomial fitted to measurement of main lobe;

GMRT — VLA Airy disk scaled to 45.0m;

IRAMPDB — Airy disk for dish of 15m with a blockage of 1m;

NRAO12M — VLA beam scaled to 12m;

OVRO — VLA Airy disk scaled to 10.4m;

SMA — Spheroidal function fit to FWHM;

WSRT — polynomial fitted to measurement of main lobe;

If the telescope name is unknown, or is CARMA or ALMA, then the DISH_DIAMETER in the ANTENNA table is used with a scaled VLA pattern.

Note that for the purposes of mosaicing in clean, the primary beams that are Airy or spheroidal are best-behaved (see §5.3.14).

5.3 Deconvolution using CLEAN (clean)

To create an image and then deconvolve it with the CLEAN algorithm, use the clean task. This task will work for single-field data, or for multi-field mosaics (§5.3.14). BETA ALERT: There is now an experimental feature to image data taken with “heterogeneous” arrays with non-identical dish sizes (§5.3.15).

The clean task uses many of the common imaging parameters. These are described above in §5.2. There are also a number of parameters specific to clean. These are listed and described below.

The default inputs to clean are:

```python
# clean :: Calculates a deconvolved image with a selected clean algorithm
vis = '' # name of input visibility file (MS)
imagename = '' # Pre-name of output images
field = '' # Field Name
```
The `clean` task will produce a number of output images based on the root name given in `imagename`. These include:

- `<imagename>.clean.image` # the restored image
- `<imagename>.clean.flux` # the effective response (e.g. for pbcor)
- `<imagename>.clean.flux.pbcoverage` # the PB coverage (ftmachine='mosaic' only)
- `<imagename>.clean.model` # the model image
- `<imagename>.clean.residual` # the residual image
- `<imagename>.clean.psf` # the synthesized (dirty) beam

**BETA ALERT:** The `<imagename>.clean.flux.pbcoverage` image is new in Patch 4 version 2.4.0 and reflects the unweighted primary beam coverage (without weighting or gridding kernel factors) used for the `minpb` cutoff (§5.3.7). This is produced only for `imagermode='mosaic'` with `ftmachine='mosaic'`.

The `mode`, `psfmode`, `imagermode`, and `weighting` parameters open up other sub-parameters. These are detailed in the common imaging task parameters section (§5.2).

A typical setup for `clean` on the NGC5921 dataset, after setting parameter values, might look like:

```python
vis = 'ngc5921.usecase.ms.contsub' # Name of input visibility file
imagename = 'ngc5921.usecase.clean' # Pre-name of output images
field = '0' # Field Name
spw = '' # Spectral windows:channels: '' is all
selectdata = False # Other data selection parameters
mode = 'channel' # Type of selection (mfs, channel, velocity, frequency)
```
CHAPTER 5. SYNTHESIS IMAGING

nchan = 46 # Number of channels (planes) in output image
start = 5 # first input channel to use
width = 1 # Number of input channels to average
interpolation = 'nearest' # Spectral interpolation (nearest, linear, cubic)
niter = 6000 # Maximum number of iterations
gain = 0.1 # Loop gain for cleaning
threshold = 8.0 # Flux level to stop cleaning. Must include units
psfmode = 'clark' # method of PSF calculation to use during minor cycles
imagermode = '' # Use csclean or mosaic, or image-plane only if ''
multiscale = [] # set deconvolution scales (pixels)
interactive = False # use interactive clean (with GUI viewer)
mask = [108, 108, 148, 148] # cleanbox(es), mask image(s), and/or region(s)
imsize = [256, 256] # x and y image size in pixels
cell = [15.0, 15.0] # x and y cell size. default unit arcsec
phasescenter = '' # Image phase center: position or field index
restfreq = '' # rest frequency to assign to image (see help)
stokes = 'I' # Stokes params to image (eg I,IV, QU, IQUV)
weighting = 'briggs' # Weighting to apply to visibilities
robust = 0.5 # Briggs robustness parameter
npixels = 0 # uv-cell size in pixels 0=> field of view
uvtaper = False # Apply additional uv tapering of visibilities.
modelimage = '' # Name of model image(s) to initialize cleaning
restoringbeam = ['] # Output Gaussian restoring beam for CLEAN image
pbcor = False # Output primary beam-corrected image
minpb = 0.1 # Minimum PB level to use
async = False

An example of the clean task to create a continuum image from many channels is given below:

clean(vis='ggtau.1mm.split.ms', # Use data in ggtau.1mm.split.ms
       imagename='ggtau.1mm', # Name output images 'ggtau.1mm.*' on disk
       psfmode='clark', # Use the Clark CLEAN algorithm
       imagermode='', # Do not mosaic or use csclean
       mask='', # Do not use clean box or mask
       niter=500, gain=0.1, # Iterate 500 times using gain of 0.1
       mode='mfs', # multi-frequency synthesis (combine channels)
       spw='0~2:2~57', # Combine channels from 3 spectral windows
       field='0', #
       stokes='I', # Image stokes I polarization
       weighting='briggs', # Use Briggs robust weighting
       rmode='norm', robust=0.5, # with robustness parameter of 0.5
       cell=[0.1,0.1], # Using 0.1 arcsec pixels
       imsize=[256,256]) # Set image size = 256x256 pixels

This example will clean the entire inner quarter of the primary beam. However, if you want to
limit the region over which you allow the algorithm to find clean components then you can make a
deconvolution region (or mask). To create a deconvolution mask, use the makemask task and input
that mask as a keyword into the task above.
Or you can set up a simple cleanbox region. To do this, make a first cut at the image and clean the inner quarter. Then use the viewer to look at the image and get an idea of where the emission is located. You can use the viewer adjustment panel to view the image in pixel coordinates and read out the pixel locations of your cursor.

Then, you can use those pixel read-outs you just go to define a clean box region where you specify the bottom-left-corner (blc) x & y and top-right-corner x& y locations. For example, say you have a continuum source near the center of your image between blcx, blcy, trcx, trcy = 80, 80, 120, 120. Then to use this region:

```plaintext
  cleanbox=[80,80,120,120]  # Set the deconvolution region as a simple box in the center.
```

The following are the clean specific parameters and their allowed values, followed by a description of carrying out interactive cleaning.

### 5.3.1 Parameter psfmode

The psfmode parameter chooses the “algorithm” that will be used to calculate the synthesized beam for use during the minor cycles in the image plane. The value types are strings. Allowed choices are ‘clark’ (default) and ‘hogbom’.

#### 5.3.1.1 The clark algorithm

In the ‘clark’ algorithm, the cleaning is split into minor and major cycles. In the minor cycles only the brightest points are cleaned, using a subset of the point spread function. In the major cycle, the points thus found are subtracted correctly by using an FFT-based convolution. This algorithm is reasonably fast. Also, for polarization imaging, Clark searches for the peak in $I^2 + Q^2 + U^2 + V^2$.

#### 5.3.1.2 The hogbom algorithm

The hogbom algorithm is the “Classic” image-plane CLEAN, where model pixels are found iteratively by searching for the peak. Each point is subtracted from the full residual image using the shifted and scaled point spread function. In general, this is not a good choice for most imaging problems (clark or csclean are preferred) as it does not calculate the residuals accurately. But in some cases, with poor uv-coverage and/or a PSF with bad sidelobes, the Hogbom algorithm will do better as it uses a smaller beam patch. For polarization cleaning, Hogbom searches for clean peak in $I, Q, U,$ and $V$ independently.

#### 5.3.1.3 The clarkstokes algorithm

In the ‘clarkstokes’ algorithm, the Clark psf (§5.3.1.1) is used, but for polarization imaging the Stokes planes are cleaned sequentially for components instead of jointly as in ‘clark’. This means
that this is the same as 'clark' for Stokes I imaging only. This option can also be combined with 
imagermode='csclean' (§5.3.4).

5.3.2 The multiscale parameter

**BETA ALERT:** The multiscale option is currently under development and should be used with caution and be considered as an “experimental” algorithm. The multi-scale CLEAN method is known to need careful tuning in order to properly converge. However, currently the only control for multiscale in the clean task is the setting of the scales.

To activate multi-scale mode, specify a non-blank list of scales in the multiscale parameter. e.g.

```
multiscale = [0,3,10,30]  # Four scales including point sources
```

These are given in numbers of pixels, and specify FWHM of the Gaussians used to compute the filtered images.

Setting the multiscale parameter to a non-empty list opens up the sub-parameter:

```
multiscale = [0, 3, 10, 30] # set deconvolution scales (pixels)
negcomponent = -1 # Stop if largest scale finds this many neg components
```

The negcomponent sub-parameter is here to set the point at which the clean terminates because of negative components. For negcomponent > 0, component search will cease when this number of negative components are found at the largest scale. If negcomponent = -1 then component search will continue even if the largest component is negative.

The CASA multi-scale algorithm uses “Multi-scale CLEAN” to deconvolve using delta-functions and circular Gaussians as the basis functions for the model, instead of just delta-functions or pixels as in the other clean algorithms. This algorithm is still in the experimental stage, mostly because we are working on better algorithms for setting the scales for the Gaussians. The sizes of the Gaussians are set using the scales sub-parameter.

We are working on defining a better algorithm for scale setting. In the toolkit, there is an nscale argument which sets scales

\[
\theta_i = \theta_{bmin} 10^{(i-N/2)/2}
\]

where \(N = \text{nscales} \) and \(\theta_{bmin}\) is the fitted FWHM of the minor axis of the CLEAN beam.

5.3.3 Parameter gain

The gain parameter sets the fraction of the flux density in the residual image that is removed and placed into the clean model at each minor cycle iteration. The default value is gain = 0.1 and is suitable for a wide-range of imaging problems. Setting it to a smaller gain per cycle, such as gain = 0.05, can sometimes help when cleaning images with lots of diffuse emission. Larger values, up to gain=1, are probably too aggressive and are not recommended.
5.3.4 Parameter imagermode

This choose the mode of operation of clean, either as single-field deconvolution using image-plane major and minor cycles only (imagermode=''), single-field deconvolution using Cotton-Schwab (CS) residual visibilities for major cycles (imagermode='csclean'), or multi-field mosaics using CS major cycles (imagermode='mosaic').

In the default mode (imagermode=''), the major and minor clean cycles work off of the gridded FFT dirty image, with residuals updated using the PSF calculation algorithm set by the psfmode parameter (§5.3.1). This method is not recommended for high dynamic range or high fidelity imaging applications, but can be significantly faster than CS clean. Note that for this option only, if mask=''' (no mask or box set) then it will clean the inner quarter of the image by default.

The csclean choice specifies the Cotton-Schwab algorithm. This opens up the sub-parameters

\[
\begin{align*}
\text{imagermode} & = \text{``csclean''} & \# \text{ Use csclean or mosaic. If '',' use psfmode} \\
\text{cyclefactor} & = 1.5 & \# \text{ Change depth in between of csclean cycle} \\
\text{cyclespeedup} & = -1 & \# \text{ Cycle threshold doubles in this number of iterations}
\end{align*}
\]

These options are explained below. In the CS mode, cleaning is split into minor and major cycles. For each field, a minor cycle is performed using the PSF algorithm specified in psfmode (§5.3.1). At major-cycle breakpoints, the points thus found are subtracted from the original visibilities. A fast variant does a convolution using a FFT. This will be faster for large numbers of visibilities. If you want to be extra careful, double the image size from that used for the Clark clean and set a
mask to clean only the inner quarter or less (this is not done by default). This is probably the best choice for high-fidelity deconvolution of images without lots of large-scale structure.

Note that when using the Cotton-Schwab algorithm with a threshold (§5.3.12), there may be strange behavior when you hit the threshold with a major cycle. In particular, it may be above threshold again at the start of the next major cycle. This is particularly noticeable when cleaning a cube, where different channels will hit the threshold at different times.

**BETA ALERT:** You will see a warning message in the logger, similar to this:

Zero Pixels selected with a Flux limit of 0.000551377 and a maximum Residual of 0.00751239

whenever it find 0 pixels above the threshold. This is normal, and not a problem, if you’ve specified a non-zero threshold. On the other hand, if you get this warning with the threshold set to the default of ‘0Jy’, then you should look carefully at your inputs or your data, since this usually means that the masking is bad.

The option `imagermode='mosaic'` is for multi-field mosaics. This choice opens up the sub-parameters

```
imagermode   = 'mosaic'   # Use csclean or mosaic. If '', use psfmode
mosweight    = False      # Individually weight the fields of the mosaic
ftmachine    = 'mosaic'   # Gridding method for the image
scaltypetype = 'SAULT'    # Controls scaling of pixels in the image plane.
cyclefactor  = 1.5        # change depth in between of csclean cycle
cyclespeedup = -1         # Cycle threshold doubles in this number of iteration
```

These options are explained below.

### 5.3.4.1 Sub-parameter cyclefactor

This sub-parameter is activated for `imagermode='csclean'` and `mosaic'`.

The `cyclefactor` parameter allows the user to change the threshold at which the deconvolution cycle will stop and then degrid and subtract the model from the visibilities to form the residual. This is with respect to the breaks between minor and major cycles that the clean part would normally force. Larger values force a major cycle more often.

This parameter in effect controls the threshold used by CLEAN to test whether a major cycle break and reconciliation occurs:

```
cycle threshold = cyclefactor * max sidelobe * max residual
```

**Inside the Toolkit:**

The `im.setmfcontrol` method sets the parameters that control the cycles and primary beam used in mosaicing.
If your uv-coverage results in a poor PSF, then you should reconcile often (a cyclefactor of 4 or 5); For reasonable PSFs, use cyclefactor in the range 1.5 to 2.0. For good PSFs, or for faster cleaning at the expense of some fidelity, we recommend trying a lower value, e.g. cyclefactor = 0.25, which at least in some of our mosaicing tests led to a speedup of around a factor of two with little change in residuals.

5.3.4.2 Sub-parameter cyclespeedup

This sub-parameter is activated for imagermode='csclean' and 'mosaic'.

The cyclespeedup parameter allows the user to let clean to raise the threshold at which a major cycle is forced if it is not converging to that threshold. To do this, set cyclespeedup to an integer number of iterations at which if the threshold is not reached, the threshold will be doubled. See cyclefactor above for more details. By default this is turned off (cyclespeedup = -1). In our tests, a value like cyclespeedup = 50 has been used successfully.

5.3.4.3 Sub-parameter ftmachine

This sub-parameter is activated for imagermode='mosaic'.

The ftmachine parameter controls the gridding method and kernel to be used to make the image. A string value type is expected. Choices are: 'ft', 'sd', 'both', or 'mosaic' (the default).

The 'ft' option uses the standard gridding kernel (as used in clean).

The 'sd' option forces gridding as in single-dish data.

For combining single-dish and interferometer MS in the imaging, the 'both' option will allow clean to choose the ‘ft’ or ‘sd’ machines as appropriate for the data.

The 'mosaic' option (the default) uses the Fourier transform of the primary beam (the aperture cross-correlation function in the uv-plane) as the gridding kernel. This allows the data from the multiple fields to be gridded down to a single uv-plane, with a significant speed-up in performance in most (non-memory limited) cases. The effect of this extra convolution is an additional multiplication (apodization) by the primary beam in the image plane. This can be corrected for, but does result in an image with optimal signal to noise ratio across it.

The primary beams used in CASA are described in §5.2.13.

BETA ALERT: Note that making a non-square image (e.g. using unequal values in imsize) for ftmachine='mosaic' will grid the data into a uv-plane with correspondingly non-square cells. This has not been extensively tested, and may results in undesired image artifacts. We recommend that the user make square mosaic images when possible, but in principle non-square images should work.

Inside the Toolkit:
The im.setoptions method sets the parameters relevant to mosaic imaging, such as the ftmachine.
5.3.4.4 Sub-parameter mosweight

If mosweight=True then individual mosaic fields will receive independent weights, which will give optimum signal to noise ratio.

If mosweight=False then the data will be weighted so that the signal-to-noise ratio is as uniform as possible across the mosaic image.

5.3.4.5 Sub-parameter scaletype

The scaletype parameter controls weighting of pixels in the image plane. This sub-parameter is activated for imagermode='mosaic'.

Inside the Toolkit:
The im.setmfcontrol method gives more options for controlling the primary beam and noise across the image.

The default scaletype='PBCOR' scales the image to have the correct flux scale across it (out to the beam level cutoff minpb). This means that the noise level will vary across the image, being increased by the inverse of the weighted primary beam responses that are used to rescale the fluxes.

This option should be used with care, particularly if your data has very different exposure times (and hence intrinsic noise levels) between the mosaic fields.

If scaletype='SAULT' then the image will be scaled so as to have constant noise across it. This means that the point source response function varies across the image attenuated by the weighted primary beam(s). However, this response is output in the .flux image and can be later used to correct this.

Note that this scaling as a function of position in the image occurs after the weighting of mosaic fields specified by mosweight and implied by the gridding weights (ftmachine and weighting).

5.3.4.6 The threshold revisited

For mosaics, the specification of the threshold is not straightforward, as it is in the single field case. This is because the different fields can be observed to different depths, and get different weights in the mosaic. For efficiency, clean does its component search on a weighted and scales version of the sky.

For ftmachine='ft', the minor cycles of the deconvolution are performed on an image that has been weighted to have constant noise, as in 'SAULT' weighting (see §5.3.4.5). This is equivalent to making a dirty mosaic by coadding dirty images made from the individual pointings with a sum of the mosaic contributions to a given pixel weighted by so as to give constant noise across the image. This means that the flux scale can vary across the mosaic depending on the effective noise (higher weighted regions have lower noise, and thus will have higher “fluxes” in the ‘SAULT’ map). Effectively, the flux scale that threshold applies to is that at the center of the highest-weighted mosaic field, with higher-noise regions down-scaled accordingly. Compared to the true
sky, this image has a factor of the PB, plus a scaling map (returned in the .flux image). You will
preferentially find components in the low-noise regions near mosaic centers.

When ftmachine=’mosaic’, the underlying deconvolution is performed on a constant signal-to-
oise image. This is equivalent to a dirty mosaic that is formed by coadding dirty images made
from the individual fields after apodizing each by the PB function. Thus compared to the true sky,
this has a factor of the PB^2 in it. You will thus preferentially find components in the centers of the
mosaic fields (even more so than in the ’ft’ mosaics).

Both these cases should have the same flux scale in the centers of the lowest-noise pointings in the
mosaic. This is where the threshold units match those in the image being used in the minor cycle.

**BETA ALERT:** This is fairly complicated, and we are working on explaining this better and
possibly making this more straightforward to specify.

### 5.3.5 Parameter interactive

If interactive=True is set, then an interactive window will appear at various “cycle” stages while
you clean, so you can set and change mask regions. These breakpoints are controlled by the
npercycle sub-parameter which sets the number of iterations of clean before stopping.

```
interactive = True  # use interactive clean (with GUI viewer)
npercycle = 100     # Number of iterations before interactive prompt
```

**BETA ALERT:** npercycle is currently the only way to control the breakpoints in interactive
clean.

See the example of interactive cleaning in §5.3.13.

### 5.3.6 Parameter mask

The mask parameter takes a list of elements, each of which can be a list of coordinates specifying a
box, or a string pointing to the name of a cleanbox file, mask image, or region file. These are used
by CLEAN to define a region to search for components.

Note that for imagermode='' (§5.3.4) the default with mask='' is to restrict clean to the inner
quarter of the image.

#### 5.3.6.1 Setting clean boxes

If mask is given a list, these are taken to be pixel coordinates for the blc and trc (bottom-left and
top-right corners) of one or more rectangular boxes. Each box is a four element list. For example,

```
mask = [ [110,110,150,145], [180,70,190,80] ]
```

defines two boxes.
5.3.6.2 Using clean box files

You can provide mask a string with the name of an ASCII file containing the BLC, TRC of the boxes with one box per line. Each line should contain five numbers

\[ <\text{fieldindex}> \ <\text{blc-x}> \ <\text{blc-y}> \ <\text{trc-x}> \ <\text{trc-y}> \]

with whitespace separators. Currently the \textit{<fieldindex>} is ignored.

Here is an example cleanbox file:

```
CASA <21>: !cat mycleanbox.txt
IPython system call: cat mycleanbox.txt
1 108 108 148 148
2 160 160 180 180
```

NOTE: In future patches we will include options for the specification of circular and polygonal regions in the cleanbox file, as well as the use of world coordinates (not just pixel) and control of plane ranges for the boxes. For now, use the mask mechanism for more complicated CLEAN regions.

5.3.6.3 Using clean mask images

You can give the mask parameter a string containing the name of a mask image to be used for CLEAN to search for components. You can use the \texttt{makemask} task to construct this mask, or use one made using \texttt{interactive=True} ([§5.3.5]).

5.3.6.4 Using region files

You can give the mask parameter a string pointing to a file that describes a region. This region file can be generated in the viewer ([§7]).

5.3.7 Parameter minpb

The \texttt{minpb} parameter sets the level down to which the primary beam (or more correctly the voltage patterns in the array) can go and have a given pixel included in the image. This is important as it defines where the edge of the visible image or mosaic is. The default is 0.1 or equivalent to the 10% response level. If there is alot of emission near the edge, then set this lower if you want to be able to clean it out.

NOTE: The \texttt{minpb} parameter is the level in the “primary beam” (PB) at which the cut is made. If you are using \texttt{ftmachine='mosaic'} ([§5.3.4.3]), this will show up in the .flux.pbcovimage image (new in version 2.4.0). See the discussion of threshold ([§5.3.4.6]) for related issues.
5.3.8 Parameter modelimage

The `modelimage` parameter specifies the name(s) of one or more input starting image(s) to use to calculate the first residual before cleaning. These are used in addition to any image with a name defaulting from the `imagename` root (e.g. on a restart). The output model will contain this model plus clean components found during deconvolution.

If the units of the image are Jy/pixel, then this is treated as a model image.

If the units of the image are Jy/beam or Jy per solid angle, then this is treated as a “single-dish” image and rescaled by the resolution (in the `beam` image header keyword). Inclusion of the SD image here is superior to feathering it in later. See §5.5 for more information on feathering.

5.3.9 Parameter niter

The `niter` parameter sets the maximum total number of minor-cycle CLEAN iterations to be performed during this run of `clean`. If restarting from a previous state, it will carry on from where it was. Note that the `threshold` parameter can cause the CLEAN to be terminated before the requested number of iterations is reached.

5.3.10 Parameter pbcor

The `pbcor` parameter controls whether the final `image` is scaled to correct for the Primary Beam of the array or not.

If `pbcor=False` (the default), then no such scaling is done and the image is in whatever “raw” scaling used by the `imagermode` algorithm underneath. For single-field cleaning with `imagermode='` or `'csclean'`, this is the standard constant-noise image. If `imagermode='mosaic'`, then this is the 'SAULT' scaled image (regardless of what `scaletype` is set to).

If `pbcor=True`, the at the end of deconvolution and imaging the “raw” image is rescaled by dividing by the noise and PB correction image. This is what is output by `clean` as the `.flux` image.

Note that regardless of what you set `pbcor` to, you can recover the other option using `immath` (§6.5) to either multiply or divide by the `.flux` image.

5.3.11 Parameter restoringbeam

The `restoringbeam` parameter allows the user to set a specific Gaussian restoring beam to make the final restored `image` from the final `.model` and residuals.

If `restoringbeam='` (the default), then the restoring beam is calculated by fitting to the PSF (e.g. the `.psf` image). For a mosaic, this is at the center of the field closest to the `phasecenter`.

To specify a restoring beam, provide `restoringbeam` a list of `[bmajor, bminor, bpositionangle]` which are the parameters of an elliptical Gaussian. The default units are in arc-seconds for `bmajor`, `bminor` components and degrees for the `bpa` component.
For example,

```plaintext
restoringbeam=['10arcsec'] # circular Gaussian FWHM 10"
restoringbeam=['10.0','5.0','45.0deg'] # 10"x5" at PA=45 degrees
```

### 5.3.12 Parameter threshold

The `threshold` parameter instructs `clean` to terminate when the maximum (absolute?) residual reaches this level or below. Note that it may not reach this residual level due to the value of the `niter` parameter which may cause it to terminate early.

If `threshold` is given a floating-point number, then this is the threshold in milli-Jansky.

You can also supply a flux density *quanta* to threshold, e.g.

```plaintext
threshold = '8.0mJy'
threshold = '0.008Jy'
```

(these do the same thing).

### 5.3.13 Interactive Cleaning — Example

If `interactive=True` is set, then an interactive window will appear at various “cycle” stages while you clean, so you can set and change mask regions. These breakpoints are controlled by the `npercycle` sub-parameter which sets the number of iterations of clean before stopping.

The window controls are fairly self-explanatory. It is basically a form of the viewer. A close-up of the controls are shown in Figure 5.1 and an example can be found in Figures 5.2–5.4. You assign one of the drawing functions (rectangle or polygon, default is rectangle) to the right-mouse button (usually), then use it to mark out regions on the image. Zoom in if necessary (standard with the left-mouse button assignment). Double-click inside the marked region to add it to the mask. If you want to reduce the mask, click the Erase radio button (rather than Add), then mark and select as normal. When finished setting or changing your mask, click the green clockwise arrow “Continue Cleaning” Next Action button. If you want to finish your clean with no more changes to the mask, hit the blue right arrow “Apply mask edits and proceed with non-interactive clean” button. If you want to terminate the clean, click the red X “Stop deconvolving now” button.

While stopped in an interactive step, you can change a number of control parameters in the boxes provided at the left of the menu bar. The main use of this is to control how many iterations before the next breakpoint (initially set to `npercycle`), how many cycles before completion (initially equal to `niter/npercycle`), and to change the `threshold` for ending cleaning. Typically, the user would start with a relatively small number of iterations (50 or 100) to clean the bright emission in tight mask regions, and then increase this as you get deeper and the masking covers more of the emission region. For extended sources, you may end up needing to clean a large number of components (10000 or more) and thus it is useful to set `niter` to a large number to begin with — you can always terminate the clean interactively when you think it is done. Note that if you
CHAPTER 5. SYNTHESIS IMAGING

Figure 5.2: Screen-shots of the interactive clean window during deconvolution of the VLA 6m Jupiter dataset. We start from the calibrated data, but before any self-calibration. In the initial stage (left), the window pops up and you can see it dominated by a bright source in the center. Next (right), we zoom in and draw a box around this emission. We have also at this stage dismissed the tape deck and Position Tracking parts of the display (§7.2.1) as they are not used here. We have also changed the iterations to 30 for this boxed clean. We will now hit the Next Action Continue Cleaning button (the green clockwise arrow) to start cleaning.

change iterations you may also want to change cycles or your clean may terminate before you expect it to.

For strangely shaped emission regions, you may find using the polygon region marking tool (the second from the right in the button assignment toolbar) the most useful.

See the example of cleaning and self-calibrating the Jupiter 6cm continuum data given below in Appendix F.2. The sequence of cleaning starting with the “raw” externally calibrated data is shown in Figures F.2 – F.4.

The final result of all this cleaning for Jupiter is shown in Figure 5.5. The viewer (§7) was used to overplot the polarized intensity contours and linear polarization vectors calculated using immath (§6.5) on the total intensity. See the following chapters on how to make the most of your imaging results.
Figure 5.3: We continue in our interactive cleaning of Jupiter from where Figure 5.2 left off. In the first (left) panel, we have cleaned 30 iterations in the region previously marked, and are zoomed in again ready to extend the mask to pick up the newly revealed emission. Next (right), we have used the Polygon tool to redraw the mask around the emission, and are ready to Continue Cleaning for another 100 iterations.

For spectral cube images you can use the tapedeck to move through the channels. You also use the panel with radio buttons for choosing whether the mask you draw applies to the Displayed Plane or to All Channels. See Figure 5.6 for an example. Note that currently the Displayed Plane option is set by default. This toggle is unimportant for single-channel images or mode='mfs'.

Advanced Tip: Note that while in interactive clean, you are using the viewer. Thus, you have the ability to open and register other images in order to help you set up the clean mask. For example, if you have a previously cleaned image of a complex source or mosaic that you wish to use to guide the placement of boxes or polygons, just use the Open button or menu item to bring in that image, which will be visible and registered on top of your dirty residual image that you are cleaning on. You can then draw masks as usual, which will be stored in the mask layer as before. Note you can blink between the new and dirty image, change the colormap and/or contrast, and carry out other standard viewer operations. See § 7 for more on the use of the viewer.

BETA ALERT: Currently, interactive spectral line cleaning is done globally over the cube, with halts for interaction after searching all channels for the requested npercycle total iterations. It is
Figure 5.4: We continue in our interactive cleaning of Jupiter from where Figure 5.3 left off. In the first (left) panel, it has cleaned deeper, and we come back and zoom in to see that our current mask is good and we should clean further. We change `npercycle` to 500 (from 100) in the box at upper right of the window. In the final panel (right), we see the results after this clean. The residuals are such that we should terminate the clean using the red X button and use our model for self-calibration.

more convenient for the user to treat the channels in order, cleaning each in turn before moving on. This will be implemented in an upcoming update.

5.3.14 Mosaic imaging

The `clean` task contains the capability to image multiple pointing centers together into a single “mosaic” image. This ability is controlled by setting `imagermode='mosaic'` (§5.3.4).

The key parameter that controls how `clean` produces the mosaic is the `ftmachine` sub-parameter (§5.3.4.3). For `ftmachine='ft'`, `clean` will perform a weighted combination of the images produced by transforming each mosaic pointing separately. This can be slow, as the individual sub-images must be recombined in the image plane. **NOTE:** this option is preferred for data taken with sub-optimal mosaic sampling (e.g. fields too far apart, on a sparse irregular pattern, etc.).
Figure 5.5: After clean and self-calibration using the intensity image, we arrive at the final polarization image of Jupiter. Shown in the viewer superimposed on the intensity raster is the linear polarization intensity (green contours) and linear polarization B-vectors (vectors). The color of the contours and the sampling and rotation by 90 degrees of the vectors was set in the Display Options panel. A LEL expression was used in the Load Data panel to mask the vectors on the polarized intensity.

The primary beams used in CASA are described in §5.2.13. If `ftmachine='mosaic'`, then the data are gridded onto a single uv-plane which is then transformed to produce the single output image. This is accomplished by using a gridding kernel that approximates the transform of the primary beam pattern. Note that for this mode the `<imagename>.flux` image includes this convolution kernel in its effective weighted response pattern (needed to “primary-beam correct” the output image). For this mode only, an additional image `<imagename>.flux.pbcoverage` is produced that is the primary-beam coverage only used to compute the `minpb` cutoff (§5.3.7).

**BETA ALERT:** In order to avoid aliasing artifacts for `ftmachine='mosaic'` in the mosaic image, due to the discrete sampling of the mosaic pattern on the sky, you should make an image in which...
the desired unmasked part of the image (above minpb) lies within the inner quarter. In other words, make an image twice as big as necessary to encompass the mosaic.

It is also important to choose an appropriate phasecenter for your output mosaic image (§ section:im.pars.phasecenter).

An example of a simple mosaic clean call is shown below:
CHAPTER 5. SYNTHESIS IMAGING

Another example of mosaic imaging, this time using 3mm BIMA data, is given in Appendix F.3.

5.3.15 Heterogeneous imaging

The clean task and underlying tools can now handle cases where there are multiple dish sizes, and thus voltage patterns and primary beams, in the array. This is effected by using the dish sizes stored in the ANTENNA sub-table of the MS. Depending on how the data was written and imported into CASA, the user may have to manually edit this table to insert the correct dish sizes (e.g. using browsetable or the tb table tool).

BETA ALERT: This feature is new in Patch 3, and has not been extensively tested. Currently, this works only for an MS where the OBSERVATORY keyword is CARMA, ALMA, or is unknown. You must set imagermode='mosaic' with ftmachine='mosaic', even when imaging a single field, to use this feature. This will be improved, and made easier to set and use, in future releases.

5.3.16 Polarization imaging

The clean task handles full and partial Stokes polarization imaging through the setting of the stokes parameter (§ 5.2.9). The subsequent deconvolution of the polarization planes of the image and the search for clean components is controlled by the psfmode parameter (§ 5.3.1). If the stokes parameter includes polarization planes other than I, then choosing psfmode='hogbom' (§ 5.3.1.2) or psfmode='clarkstokes' (§ 5.3.1.3) will clean (search for components) each plane sequentially, while psfmode='clark' (§ 5.3.1.1) will deconvolve jointly.

The interactive clean example given above (§ 5.3.13) shows a case of polarization imaging. You can also find the script for this example in Appendix F.2.
5.4 Wide-field imaging and deconvolution (widefield)

When imaging sufficiently large angular regions, the sky can no longer be treated as a two-dimensional plane and the use of the standard clean task will produce distortions around sources that become increasingly severe with increasing distance from the phase center. In this case, one must use a “wide-field” imaging algorithm such as w-projection or faceting.

When is wide-field imaging needed? It depends on the expected dynamic range the image. In order to keep the phase error associated with the sky/array curvature less than about 5° (good to about 500:1 dynamic range), use the following table, suitably scaled, for guidance:

<table>
<thead>
<tr>
<th>Wavelength</th>
<th>Radius of image</th>
</tr>
</thead>
<tbody>
<tr>
<td>6 cm</td>
<td>1.4 arcmin</td>
</tr>
<tr>
<td>20 cm</td>
<td>2.6 arcmin</td>
</tr>
<tr>
<td>90 cm</td>
<td>5.3 arcmin</td>

</table>

Radius of image ~ \( \sqrt{\text{Wavelength} \times \text{phase error} / \text{Maximum baseline}} \)

If a relatively small image is being made, but there are outliers sources beyond the above limits, then widefield should also be used.

The task widefield has been introduced for this purpose. This is currently a prototype task that can be used to make and deconvolve a wide-field image (e.g. from low frequency data). It contains most, but not all, of the flexibility of clean. The w-term is handled using a combination of w-projection and faceting. Besides making large area undistorted images, widefield can be used to outlying fields to image isolated regions (e.g. containing bright confusing sources) distant from the field center.

The inputs for widefield are:

```python
# widefield :: Wide-field imaging and deconvolution with selected algorithm
vis = [''] # name of input visibility file
imagename = # Pre-name of output images
outlierfile = '' # Text file with image names, sizes, centers
field = '' # Field Name
spw = '' # Spectral windows:channels: '' is all
selectdata = False # Other data selection parameters
mode = 'mfs' # Type of selection (mfs, channel, velocity, frequency)
niter = 500 # Maximum number of iterations
gain = 0.1 # Loop gain for cleaning
threshold = '0.0Jy' # Flux level to stop cleaning. Must include units
psfmode = 'clark' # Algorithm to use (clark, hogbom)
ftmachine = 'wproject' # Gridding method for the image (wproject, ft)
wprojplanes = 256 # Number of planes to use in w-convolution function
facets = 1 # Number of facets along each axis in main image only
```
CHAPTER 5. SYNTHESIS IMAGING

multiscale = [] # set deconvolution scales (pixels), default: single scale
interactive = False # use interactive clean (with GUI viewer)
mask = [] # cleanbox(es), mask image(s), and/or region(s)
imsize = [256, 256] # Image size in pixels (nx,ny), symmetric for single value
cell = ['1.0arcsec', '1.0arcsec'] # The image cell size in arcseconds [x,y].
phasedcenter = '' # Field Identifier or direction of the image phase center
restfreq = '' # rest frequency to assign to image (see help)
stokes = 'I' # Stokes params to image (I,IV,QU,QUV,RR,LL,XX,YY,RRLL,XXYY)
weighting = 'natural' # Weighting to apply to visibilities
cyclefactor = 1.5 # Change the threshold at which the deconvolution cycle will stop,
# degrid, and subtract from the visibilities.
cyclespeedup = -1 # Cycle threshold doubles in this number of iterations
uvtaper = False # Apply additional uv tapering of visibilities.
restoringbeam = [''] # Output Gaussian restoring beam for CLEAN image
async = False # If true the taskname must be started using widefield(...)

Most of the parameters are similar to clean and should be reviewed there. Specialized parameters
for widefield are as follows:

The task widefield can be used in two major modes: First, the w-projection mode as chosen with
ftmachine deals with the w-term (the phase associated with the sky/array curvature) internally.
Secondly, the image can be broken into many facets, each small enough so that the w-term is not
significant. These two basic methods can be combined, and are discussed below in §5.4.1.

When using widefield, the position and image size of each image must be specified. This can be
done in two ways. The first method uses input from a text file outlierfile. For example:

vis = 'wfield.ms' # name of input visibility file
imagename = 'wf' # Pre-name of output images
outlierfile = 'setup.txt' # Text file with image names, sizes, centers
imsize = [256, 256] # Image size in pixels (nx,ny), symmetric for single value
cell = ['1.0arcsec', '1.0arcsec'] # The image cell size in arcseconds [x,y].
phasedcenter = '' # Field Identifier or direction of the image phase center

The cell is identical for all fields, and imsize and phasedcenter are not used. The output image
names will be wf.main, wf.out1, etc.

The file outlierfile="setup.txt" is an AIPS-style field file used to locate outlier fields. For
example:

C main 2048 2048 13 27 20.98 43 26 28.0 # Main field with image size and phase center
C out1 128 128 13 30 52.158 43 23 08.00 # First outlier field specification etc

will make a big main image with outliers. The C in column 1 must be present, although it not
presently used.

The alternative input, needing no additional outlier file, versus imsize plus phasedcenter: is:

vis = 'wfield.ms'
imagename = 'wf'
outlierfile = 'setup.txt'
imsize = [256, 256]
cell = ['1.0arcsec', '1.0arcsec']
phasedcenter = ''

This is done by the AIPS command main.

Most of the parameters are similar to clean and should be reviewed there. Specialized parameters
for widefield are as follows:
vis = 'wfield.ms'  # name of input visibility file
imagename = 'wf'  # Pre-name of output images
outlierfile = 'image_setup.txt'  # Text file with image names, sizes, centers
imsize = [2048, 2048, 128, 128]  # Image size in pixels (nx,ny)
cell = '1.0arcsec'  # The image cell size in arcseconds [x,y].
phasescenter = ['J2000 13h27m20.98 43d26m28.0', 'J2000 13h30m52.158 43d23m08.00']

The other parameters are described in clean, and multi-scale cleaning in available. Mosaicing and MEM is not yet included in widefield.

### 5.4.1 ftmachine modes for widefield

The crucial part of widefield is the parameters under ftmachine. The three types of use are: (1) w-projection only; (2) facets only; (3) w-projection with facets.

#### 5.4.1.1 pure w-projection

The “pure” w-projection mode is invoked using ftmachine='wproject':

```
ftmachine = 'wproject'  # Gridding method for the image (wproject, ft)
wprojectplanes = 64  # Number of planes to use in wprojection convolution function
facets = 1  # Number of facets along each axis in main image only
```

A reasonable value for wprojectplanes is equal to \( n_w = B_{\text{max}} (\text{ink} \lambda) \times \text{imagewidth(inarcmin}^2)/600, \) with a minimum value of \( n_w = 16. \) The w-projection algorithm is much faster than using faceting, but it does consume a lot of memory. On most 32-bit machines with 1 or 2 Mbytes of memory, images larger than about 4000 \( \times \) 4000 cannot be made.

#### 5.4.1.2 faceting only

Faceting only mode will break the image into many small parts. This is invoked using ftmachine='ft':

```
ftmachine = 'ft'  # Gridding method for the image (wproject, ft)
facets = 7  # Number of facets along each axis in main image only
```

In this example the image is broken into 49 (7 \( \times \) 7) facets.

A reasonable value of facets is such that the image width of each facet does not need the w-term correction. The computation method with pure faceting is slow, so that wprojection is recommended.
5.4.1.3 combination of w-projection and faceting

You can also use a combination of w-projection and faceting with ftmachine='wproject':

```python
ftmachine = 'wproject' # Gridding method for the image (wproject, ft)
wprojplanes = 32 # Number of planes to use in wprojection convolution function
facets = 3 # Number of facets along each axis in main image only
```

This hybrid method allows for a smaller number of wprojplanes in order to try to conserve memory if the image size approached the memory limit of the computer. However, there is a large penalty in execution time.

5.5 Combined Single Dish and Interferometric Imaging (feather)

The term “feathering” is used in radio imaging to describe how to combine or “feather” two images together by forming a weighted sum of their Fourier transforms in the (gridded) uv-plane. Intermediate size scales are down-weighted to give interferometer resolution while preserving single-dish total flux density.

The feathering technique does the following:

1. The single-dish and interferometer images are Fourier transformed.
2. The beam from the single-dish image is Fourier transformed ($FTSDB(u, v)$).
3. The Fourier transform of the interferometer image is multiplied by $(1 - FTSDB(u, v))$. This basically down weights the shorter spacing data from the interferometer image.
4. The Fourier transform of the single-dish image is scaled by the volume ratio of the interferometer restoring beam to the single dish beam.
5. The results from 3 and 4 are added and Fourier transformed back to the image plane.

The term feathering derives from the tapering or down-weighting of the data in this technique; the overlapping, shorter spacing data from the deconvolved interferometer image is weighted down compared to the single dish image while the overlapping, longer spacing data from the single-dish are weighted down compared to the interferometer image.

The tapering uses the transform of the low resolution point spread function. This can be specified as an input image or the appropriate telescope beam for the single-dish. The point spread function for a single dish image may also be calculated using clean.

Other Packages:
The feather task is analogous to the AIPS IMERG task and the MIRIAD immerge task with option 'feather'.
CHAPTER 5. SYNTHESIS IMAGING

Advice: Note that if you are feathering large images, be advised to have the number of pixels along the X and Y axes to be composite numbers and definitely not prime numbers. In general FFTs work much faster on even and composite numbers. You may use subimage function of the image tool to trim the number of pixels to something desirable.

The inputs for feather are:

```
imagename = '' # Name of output feathered image
highres = '' # Name of high resolution (synthesis) image
lowres = '' # Name of low resolution (single dish) image
async = False # If true the taskname must be started using feather(...)```

Note that the only inputs are for images. Note that feather does not do any deconvolution but combines presumably deconvolved images after the fact.

Starting with a cleaned synthesis image and a low resolution image from a single dish telescope, the following example shows how they can be feathered:

```
feather(imagename='feather.im', # Create an image called feather.im
       highres='synth.im', # The synthesis image is called synth.im
       lowres='single_dish.im' # The SD image is called single_dish.im
)
```

Note that the single dish image must have a well-defined beam shape and the correct flux units for a model image (Jy/beam instead of Jy/pixel) so use the tasks `imhead` and `immath` first to convert if needed.

5.6 Making Deconvolution Masks (makemask)

For most careful imaging, you will want to restrict the region over which you allow CLEAN components to be found. To do this, you can create a 'deconvolution region' or 'mask' image using the `makemask` task. This is useful if you have a complicated region over which you want to clean and it will take many clean boxes to specify.

The parameter inputs for makemask are:

```
# makemask :: Derive a mask image from a cleanbox and set of imaging parameters:

cleanbox = [] # Clean box file or regions
vis = '' # Name of input visibility file (if no input image)
imagename = '' # Name of output mask images
mode = 'mfs' # Type of selection (mfs, channel, velocity)
imsize = [256, 256] # Image size in spatial pixels [x,y]
cell = [1, 1] # Cell size in arcseconds
phasedecenter = '' # Field identifier or direction of the phase center
stokes = 'I' # Stokes parameter to image (I,IV,IQU,IQUV)
field = '0' # Field ids list to use in mosaic
spw = '0' # Spectral window identifier (0-based)
```
The majority of the parameters are the standard imaging parameters (§5.2). The cleanbox parameter uses the syntax for cleanboxes as in the clean parameter mask (see §5.3.6), with the option for 'interactive' also. The imagename parameter specifies the name for the output mask image.

You can use the viewer to figure out the cleanbox blc-trc x-y settings, make the mask image, and then bring it into the viewer as a contour image over your deconvolved image to compare exactly where your mask regions are relative to the actual emission. In this example, create a mask from many cleanbox regions specified in a file on disk (cleanboxes.txt) containing

1 80 80 120 120
2 20 40 24 38
3 70 42 75 66

where each line specifies the field index and the blc x-y and trc x-y positions of that cleanbox. For example, in casapy, you can do this easily:

```
CASA <29>: !cat > cleanboxes.txt
IPython system call: cat > cleanboxes.txt
1 80 80 120 120
2 20 40 24 38
3 70 42 75 66
<CNTL-D>
CASA <30>: !cat cleanboxes.txt
IPython system call: cat cleanboxes.txt
1 80 80 120 120
2 20 40 24 38
3 70 42 75 66
```

Then, in CASA,

```
makemask(vis='source.ms',
    imagename='source.mask',
    cleanbox='cleanboxes.txt',
    mode='mfs',  # make a multi-frequency synthesis map (combine channels)
    imsize=[200,200])  # Set image size = 200x200 pixels
    cell=[0.1,0.1],  # Using 0.1 arcsec pixels
    spw='0,1,2',  # Combine channels from 3 spectral windows
    field='0',  # Use the first field in this split dataset
    stokes='I')  # Image stokes I polarization
```

This task will then create a mask image that has the 3 cleanboxes specified in the cleanboxes.txt file.

You can also specify the cleanbox as a list (of lists) of blc,trc pairs (4 veritices), e.g.

```
cleanbox = [[80, 80, 120, 120], [20, 40, 24, 38], [70, 42, 75, 66]]
```

is equivalent to the cleanboxes.txt given above. Likewise,
cleanbox = [80, 80, 120, 120]

puts in a single cleanbox.

Note that you must specify a visibility dataset and create the image properties so the mask image will have the same dimensions as the image you want to actually clean.

**BETA ALERT:** Eventually we will add functionality to deal with the creation of non-rectangular regions and with multi-plane masks. There is also no `cleanbox='interactive'` version currently available. You have to run `clean` with `cleanbox='interactive'` to generate a mask graphically.

### 5.7 Transforming an Image Model (ft)

The `ft` task will Fourier transform an image and insert the resulting model into the `MODEL_DATA` column of a Measurement Set. You can also convert a CLEAN component list to a model and insert that into the `MODEL_DATA` column. The MS `MODEL_DATA` column is used, for example, to hold the model for calibration purposes in the tasks and toolkit. This is especially useful if you have a resolved calibrator and you want to start with a model of the source before you derive accurate gain solutions. This is also helpful for self-calibration (see §5.9 below).

The inputs for `ft` are:

```plaintext
vis = '' # Name of input visibility file
fieldid = 0 # Field index identifier
field = '' # Field name list
model = '' # Name of input model image
complist = '' # Name of component list
incremental = False # Add to the existing MODEL_DATA column?
```

An example of how to do this:

```plaintext
ft(vis='n75.ms', # Start with the visibility dataset n75.ms
   field='1328', # Select field name '1328+307' (minimum match)
   model='1328.model.image') # Name of the model image you have already
```

This task will Fourier transform the model image and insert the resulting model in the `MODEL_DATA` column of the rows of the MS corresponding to the source 1328+307.

Note that after `clean`, the transform of the final model is left in the `MODEL_DATA` column so you can go directly to a self-calibration step without explicitly using `ft`. 
5.8 Image-plane deconvolution (deconvolve)

If you have only an image (obtained from some telescope) and an image of its point spread function, then you can attempt a simple image-plane deconvolution. Note that for interferometer data, full uv-plane deconvolution using clean or similar algorithm is superior!

The default inputs for deconvolve are:

```plaintext
# deconvolve :: Deconvolving a point spread function from an image

imagename = '' # Name of image to deconvolve
model = '' # Name of output image to which deconvolved components are stored
psf = '' # Name of psf or gaussian parameters if psf is assumed gaussian
alg = 'clark' # Deconvolution algorithm to use
niter = 10 # number of iteration to use in deconvolution process
gain = 0.1 # CLEAN gain parameter
threshold = '0.0Jy' # level below which sources will not be deconvolved
mask = '' # Name of image that has mask to limit region of deconvolution
async = False # if True run in the background, prompt is freed
```

The algorithm (alg) options are: 'clark', 'hogbom', 'multiscale' or 'mem'. The 'multiscale' and 'mem' options will open the usual set of sub-parameters for these methods.

5.9 Self-Calibration

Once you have a model image or set of model components reconstructed from your data using one of the deconvolution techniques described above, you can use it to refine your calibration. This is called self-calibration as it uses the data to determine its own calibration (rather than observations of special calibration sources).

In principle, self-calibration is no different than the calibration process we described earlier (§4). In effect, you alternate between calibration and imaging cycles, refining the calibration and the model as you go. The trick is you have to be careful, as defects in early stages of the calibration can get into the model, and thus prevent the calibration from improving. In practice, it is best to not clean very deeply early on, so that the CLEAN model contains correct components only.

One important thing to keep in mind is that the self-calibration relies upon having the most recent Fourier transform of the model in the MODEL_DATA column of the MS. This is indeed the case if you follow the imaging (using clean) directly by the self-calibration. If you have done something strange in between and have lost or overwritten the MODEL_DATA column (for example done some extra cleaning that you do not want to keep), then use the ft task (see §5.7 above), which fills the MODEL_DATA column with the Fourier transform of the specified model or model image.

Likewise, during self-calibration (once you have a new calibration solution) the imaging part relies upon having the CORRECTED_DATA column contain the self-calibrated data. This is done with the applycal task (§14.6.1).
The `clearcal` command can be used during the self-calibration if you need to clear the `CORRECTED_DATA` column and revert to the original `DATA`. If you need to restore the `CORRECTED_DATA` to any previous stage in the self-calibration, use `applycal` again with the appropriate calibration tables.

**BETA ALERT:** In later patches we will change the tasks so that users need not worry what is contained in the MS scratch columns and how to fill them. CASA will handle that underneath for you!

For now, we refer the user back to the calibration chapter for a reminder on how to run the calibration tasks.

See the example of cleaning and self-calibrating the Jupiter 6cm continuum data given below in Appendix F.2.

### 5.10 Examples of Imaging

See the scripts provided in Appendix F for examples of imaging. In particular, we refer the interested user to the demonstrations for:

- NGC5921 (VLA HI) — a quick demo of basic CASA spectral line cube imaging and analysis [F.1]
- Jupiter (VLA 6cm continuum polarimetry) — polarization imaging and analysis [F.2]
- NGC4826 (BIMA 3mm CO) — mosaic imaging of spectral line data [F.3]
Chapter 6

Image Analysis

Once data has been calibrated (and imaged in the case of synthesis data), the resulting image or image cube must be displayed or analyzed in order to extract quantitative information, such as statistics or moment images. In addition, there need to be facilities for the coordinate conversion of images for direct comparison. We have assembled a skeleton of image analysis tasks for this release. Many more are still under development.

The image analysis tasks are:

- **imhead** — summarize and manipulate the “header” information in a CASA image (§ 6.2)
- **imcontsub** — perform continuum subtraction on a spectral-line image cube (§ 6.3)
- **imfit** — image plane Gaussian component fitting (§ 6.4)
- **immath** — perform mathematical operations on or between images (§ 6.5)
- **immoments** — compute the moments of an image cube (§ 6.6)
- **imstat** — calculate statistics on an image or part of an image (§ 6.7)
- **imval** — extract the data and mask values from a pixel or region of an image (§ 6.8)
- **imregrid** — regrid an image onto the coordinate system of another image (§ 6.9)
- **imsmooth** — smooth images in the spectral and angular directions (§ 6.10)
- **importfits** — import a FITS image into a CASA *image* format table (§ 6.11.2)
- **exportfits** — write out an image in FITS format (§ 6.11.1)

There are other tasks which are useful during image analysis. These include:

**Inside the Toolkit:**
Image analysis is handled in the *ia* tool. Many options exist there, including region statistics and image math. See § 6.12 below for more information.
• viewer — there are useful region statistics and image cube slice and profile capabilities in
the viewer (§ 7)

We also give some examples of using the CASA Toolkit to aid in image analysis (§ 6.12).

6.1 Common Image Analysis Task Parameters

We now describe some sets of parameters are are common to the image analysis. These should
behave the same way in any of the tasks described in this section that they are found in.

6.1.1 Region Selection (box)

Area selection in the image analysis tasks is controlled by the box parameter or through the regions
parameter (§ 6.1.5).

The box parameter selects rectangular areas:

```python
box = ' ' # Select one or more box regions
# string containing blcx,blcy,trcx,trcy
# A box selection in the directional portion of an image.
# The directional portion of an image are the axes for right
# ascension and declination, for example. Boxes are specified
# by there bottom-left corner (blc) and top-right corner (trc)
# as follows: blcx, blcy, trcx, trcy;
# ONLY pixel values acceptable at this time.
# Default: none (all);
# Example: box='0,0,50,50'
# Example: box='[10,20,30,40];[100,100,150,150]'
```

To get help on box, see the in-line help

```
help(par.box)
```

6.1.2 Plane Selection (chans, stokes)

The channel, frequency, or velocity plane(s) of the image is chosen using the chans parameter:

```python
chans = ' ' # Select the channel(spectral) range
# string containing channel range
# immath, imstat, and imcontsub - takes a string listing
```
CHAPTER 6. IMAGE ANALYSIS

# of channel numbers, velocity, and/or frequency
# numbers, much like the spw parameter
# Only channel numbers acceptable at this time.
# Default: none (all);
# Example: chans='3~20'
# chans="0,3,4,8"
# chans="3~20,50,51"

The polarization plane(s) of the image is chosen with the stokes parameter:

```python
stokes = ''  # Stokes params to image (I,IV,IQU,IQUV)
# string containing Stokes selections
# Stokes parameters to image, may or may not be separated
# by commas but best if you use commas.
# Default: none (all); Example: stokes='IQUV';
# Example:stokes='I,Q'
# Options: 'I','Q','U','V',
# 'RR','RL','LR','LL',
# 'XX','YX','XY','YY',...
```

To get help on these parameters, see the in-line help

```
help(par.chans)
help(par.stokes)
```

Sometimes, as in the immoments task, the channel/plane selection is generalized to work on more than one axis type. In this case, the planes parameter is used. This behaves like chans in syntax.

### 6.1.3 Lattice Expressions (expr)

Lattice expressions are strings that describe operations on a set of input images to form an output image. These strings use the Lattice Expression Language (LEL). LEL syntax is described in detail in AIPS++ Note 223

```python
http://aips2.nrao.edu/docs/notes/223/223.html
```

**BETA ALERT:** This document was written in the context of glish-based AIPS++ and is not yet updated to CASA syntax (see below).

The expr string contains the LEL expression:

```python
expr = ''  # Mathematical expression using images
# string containing LEL expression
```
CHAPTER 6. IMAGE ANALYSIS

# A mathematical expression, with image file names.
# image file names must be enclosed in double quotes ("")
# Default: none
# Example: expr='min("image2.im")+(2*max("image1.im"))'
#
# Available functions in the expr and mask parameters:
# PI(), E(), SIN(), SINH(), ASIN(), COS(), COSH(), TAN(), TANH(),
# ATAN(), EXP(), LOG(), LOG10(), POW(), SQRT(), COMPLEX(), CONJ()
# REAL(), IMAG(), ABS(), ARG(), PHASE(), AMPLITUDE(), MIN(), MAX()
# ROUND(), ISGN(), FLOOR(), CEIL(), REBIN(), SPECTRALINDEX(), PA(),
# IIF(), INDEXIN(), REPLACE(), ...

For examples using LEL expr, see §6.5.1 below.

BETA ALERT: As of Patch 2, LEL expressions use 0-based indices.

6.1.4 Masks (mask)

The mask string contains a LEL expression (see §6.1.3 above). This string can be an on-the-fly (OTF) mask expression or refer to an image pixel mask.

```
mask = '' # Mask to be applied to the images

# string containing LEL expression

# Name of mask applied to each image in the calculation
# Default '' means no mask;
# Example: mask="ngc5921.clean.cleanbox.mask">0.5'
# mask='mask(ngc5921.clean.cleanbox.mask)'
```

Note that the mask file supplied in the mask parameter must have the same shape, same number of axes and same axes length, as the images supplied in the expr parameter, with one exception. The mask may be missing some of the axes — if this is the case then the mask will be expanded along these axes to become the same shape.

For examples using mask, see §6.5.2 below.

6.1.5 Regions (region)

The region parameter points to an ImageRegion file. An ImageRegion file can be created with the CASA viewer’s region manager (§7.3.5). Typically ImageRegion files will have the suffix `.rgn'.

If a region file is given then the box, chans, and stokes parameters will be ignored.

For example:

```
region='myimage.im.rgn'
```
6.2 Image Header Manipulation (imhead)

To summarize and change keywords and values in the “header” of your image, use the imhead task. Its inputs are:

```python
# imhead :: Lists, gets and puts image header parameters
imagename = '' # Name of input image file
mode = 'summary' # Options: get, put, summary, list, stats
async = False
```

The mode parameter controls the operation of imhead.

Setting mode='summary' will print out a summary of the image properties and the header to the logger.

Setting mode='list' prints out a list of the header keywords and values to the terminal.

The mode='get' allows the user to retrieve the current value for a specified keyword hditem:

```python
mode = 'get' # imhead options: get, put, summary, and list
hditem = '' # Header item to get or set
```

Note that to catch this value, you need to assign it to a Python variable:

```python
# Using the functional call method
myvalue = imhead('ngc5921.clean.image',mode='get',hditem='beam')
# Using globals
default('imhead')
imagename = 'ngc5921.clean.image'
mode = 'get'
hditem = 'beam'
myvalue = imhead()
```

See §1.3.3 for more on return values.

**BETA ALERT:** This has changed in Patch 2.0. In previous versions hdvalue was an output variable for mode='get'.

The mode='put' allows the user to replace the current value for a given keyword hditem with that specified in hdvalue. There are two sub-parameters that are opened by this option:

```python
mode = 'put' # imhead options: get, put, summary, and list
hditem = '' # Header item to get or set
hdvalue = '' # Value to set Header Item (hditem) to
```

**WARNING:** Be careful when using mode='put'. This task does no checking on whether the values you specify (e.g. for the axes types) are valid, and you can render your image invalid. Make sure you know what you are doing when using this option!
6.2.1 Examples for imhead

For example,

CASA <1>: imhead('ngc5921.usecase.clean.image','summary')
Summary information is listed in logger

prints in the logger:

Opened image ngc5921.usecase.clean.image

<table>
<thead>

If you choose mode='list', you get the summary in the logger and a listing of keywords and values to the terminal:

CASA <2>: imhead('ngc5921.usecase.clean.image',mode='list')

Available header items to modify:

General --
-- object N5921_2
-- telescope VLA
-- observer TEST
-- epoch "1995/04/13/00:00:00"

Retrieving restfrequency
The values for these keywords can be queried using \texttt{mode='get'}. This opens sub-parameters

\begin{verbatim}
mode    =    'get'  # Options: get, put, summary, list, stats
hditem =    ','    # header item to get or put
\end{verbatim}

Note that the \texttt{mode='get'} option returns a Python dictionary containing the current value of the \texttt{hditem}. This dictionary can be manipulated in Python in the usual manner. For example, continuing the above example:

\begin{verbatim}
CASA <3>: imagename = 'ngc5921.usecase.clean.image'
CASA <4>: mode = 'get'
CASA <5>: hditem = 'observer'
CASA <6>: hdvalue = imhead()
***
observer :: TEST

CASA <7>: print hdvalue
TEST
\end{verbatim}
You can set the values for these keywords using `mode='put'`. This opens sub-parameters

```
mode = 'put'  # Options: get, put, summary, list, stats
hditem = ''  # header item to get or put
hdvalue = ''  # header value to set (for mode=put)
```

Continuing the example further:

```
CASA <8>: mode = 'put'
CASA <9>: hdvalue = 'CASA'
CASA <10>: imhead()

CASA <11>: mode = 'list'
CASA <12>: imhead()
```

Available header items to modify:

```
General --
  -- object
  -- telescope VLA
  -- observer CASA
...
```

### 6.3 Continuum Subtraction on an Image Cube (imcontsub)

One method to separate line and continuum emission in an image cube is to specify a number of line-free channels in that cube, make a linear fit to the visibilities in those channels, and subtract the fit from the whole cube. Note that the task `uvcontsub` serves a similar purpose; see §[4.7.4](#) for a synopsis of the pros and cons of either method.

The `imcontsub` task will subtract a polynomial baseline fit to the specified channels from an image cube.

The default inputs are:

```
# imcontsub :: Continuum subtraction on images
imagename = ''  # Name of the input image
linefile = ''  # Output line image file name
contfile = ''  # Output continuum image file name
fitorder = 0  # Polynomial order for the continuum estimation
region = ''  # Image region or name to process see viewer
box = ''  # Select one or more box regions
chans = ''  # Select the channel(spectral) range
stokes = ''  # Stokes params to image (I,IV,IQU,IQUV)
async = False
```

Area selection using `box` and `region` is detailed in §[6.1.1](#) and §[6.1.5](#) respectively.

Image cube plane selection using `chans` and `stokes` are described in §[6.1.2](#)
BETA ALERT: `imcontsub` has issues when the image does not contain a spectral or stokes axis. Errors are generated when run on an image missing one or both of these axes. You will need to use the Toolkit (e.g. the `ia.adddegaxes` method) to add degenerate missing axes to the image.

6.3.1 Examples for `imcontsub`)

For example, in a cube named `cube2403` with 97 spectral line channels it has been determined that channels 0 through 17 and channels 79 through 96 are line-free. Then:

```python
default('imcontsub')

imagename = 'cube2403'
linefile = 'line2403'
contfile = 'cont2403'
fitorder = 1
chan = '0~17, 79~96'
stokes = 'I'

imcontsub()
```

will fit a first order polynomial to the visibilities in channels 0 through 17 and 79 through 96, subtract that fit from the input cube `cube2403` and write the result to the cube `line2403`. The fitted continuum itself is written to the cube `cont2403` and, if so desired, can be averaged to create a single high signal-to-noise continuum image.

6.4 Image-plane Component Fitting (imfit)

The inputs are:

```python
# imfit :: Fit 2-dimentional Gaussian(s) on image region(s)

imagename = '' # Name of the input image
box = '' # Specify one or more box regions for the fit.
region = '' # Image Region or name. Use viewer
mask = '' # Mask to be applied to the image
fixed = '' # Parameters to hold fixed (not implemented).
usecleanbeam = False # Estimate the true source size.
estfile = '' # Initial estimate of parameters (Not yet implemented).
residfile = '' # Residual image removing fit. (Not yet implemented)
async = False # If true, run asynchronously
```

BETA ALERT: This task is new to Patch 2.0 and has not been as extensively tested as the other tasks. Currently, it can fit only a single Gaussian component. This restriction will be lifted in future patches.
6.5 Mathematical Operations on an Image (immath)

The inputs are:

```python
# immath :: Perform math operations on images
outfile = '' # File where the output is saved
mode = 'evalexpr' # mode for math operation (evalexpr, spix, pola, poli)
    exp = '' # Mathematical expression using images
mask = '' # Mask to be applied to the images
region = '' # File path which contains an Image Region
box = '' # Select one or more box regions in the input images
chans = '' # Select the channel(spectral) range
stokes = '' # Stokes params to image (I,IV,IQU,IQUV)
async = False # If true run asynchronously
```

In all cases, `outfile` must be supplied with the name of the new output file to create.

The `mode` parameter selects what `immath` is to do.

The default `mode='evalexpr'` lets the user specify a mathematical operation to carry out on one or more input images. The sub-parameter `expr` contains the Lattice Expression Language (LEL) string describing the image operations. See §6.1.3 for more on LEL strings and the `expr` parameter.

Mask specification is done using the `mask` parameter. This can optionally contain an on-the-fly mask expression (in LEL) or point to an image with a pixel mask. See §6.1.4 for more on the use of the `mask` parameter. See also §6.1.3 for more on LEL strings.

Region selection is carried out through the `region` and `box` parameters. See §6.1.1 and §6.1.5 for more on area selection.

Image plane selection is controlled by `chans` and `stokes`. See §6.1.2 for details on plane selection.

**BETA ALERT:** As of Patch 2, LEL expressions (as in `expr`) use 0-based array indices.

### 6.5.1 Examples for immath

The following are examples using `immath`. Note that the image names in the `expr` are assumed to refer to existing image files in the current working directory.

#### 6.5.1.1 Simple math

Double all values in an image:

```python
immath( expr='"myimage.im"*2', outfile='double.im' )
```

Take the sine of an image and add it to another:
immath(expr='SIN("image2.im")+"image1.im"', outfile='newImage.im')

Note that the two input images used in expr need to be the same size.

Add only the plane associated with the 'V' Stokes value and the first channel together in two images:

immath(expr='"image1"+"image2"', chans='1', stokes='V')

Select a single plane (the 5th channel) of the 3-D cube and subtract it from the original image:

default('immath')
  outfile='ngc5921.chan5.image'
  expr='"ngc5921.clean.image"'
  chans='5'
go

default('immath')
  outfile='ngc5921.clean.sub5.image'
  expr='"ngc5921.clean.image"-"ngc5921.chan5.image"
go

Note that in this example the 2-D plane gets expanded out and the values are applied to each plane in the 3-D cube.

Select and save the inner 1/4 of an image for channels 40,42,44 as well as channels 10 and below:

default('immath')
  expr='"ngc5921.clean.image"'
  box='64,64,192,192'
  chans='<10;40,42,44'
  outfile='ngc5921.clean.inner'
go

BETA ALERT: Note that if chan selects more than one channel then the output image has a number of channels given by the span from the lowest and highest channel selected in chan. In the example above, it will have 45 channels. The ones not selected will be masked in the output cube. If we had set

chans = '40,42,44'

then there would be 5 output channels corresponding to channels 40,41,42,43,44 of the MS with 41,43 masked. Also, the chans='<10' selects channels 0–9.

Note that the chans syntax allows the operators '<', '<=', '>', '>='.

chans = '<17,>79'
chans = '<=16,>=80'
do the same thing.

Divide an image by another, making sure we are not dividing by zero:

\[
\text{default(}'\text{immath}'\text{)} \\
\text{expr='''orion.image''}/\text{\textbf{iif}}(''\text{my.image}''==0,1.0,''\text{my.image}''') \\
\text{outfile='my_orion.image'} \\
\text{go}
\]

Note that this will put 1.0 in the output image where the divisor image is zero. You can also just mask below a certain level in the divisor image, e.g.

\[
\text{default(}'\text{immath}'\text{)} \\
\text{expr='''orion.image''''/''my.image''[''my.image''>0.1']'} \\
\text{outfile='my_orion.image'} \\
\text{go}
\]

### 6.5.1.2 Polarization manipulation

Create a polarized intensity image from a IQUV image:

\[
\text{default( ('immath')} \\
\text{outfile='I.im'; expr='''3C138_pcal'''; stokes='I'; go();} \\
\text{outfile='Q.im'; expr='''3C138_pcal'''; stokes='Q'; go();} \\
\text{outfile='U.im'; expr='''3C138_pcal'''; stokes='U'; go();} \\
\text{outfile='V.im'; expr='''3C138_pcal'''; stokes='V'; go();} \\
\text{outfile='pol_intensity'} \\
\text{stokes=''} \\
\text{expr='sqrt('''I.im''*'I.im' + '''Q.im''*'Q.im' + '''U.im''*'U.im' + '''V.im''*'V.im' )'} \\
\text{go}
\]

### 6.5.1.3 Primary beam correction/uncorrection

In a script using \texttt{mode='evalexpr'}, you might want to assemble the string for \texttt{expr} using string variables that contain the names of files. Since you need to include quotes inside the \texttt{expr} string, use a different quote outside (or escape the string, e.g. \\
\textquote{'}). For example, to do a primary beam correction on the NGC5921 cube,

\[
imname = 'ngc5921.usecase.clean'
imagename = imname \\
... \\
clean()
\]

\[
\text{default('immath')} \\
\text{clnimage} = 'imname + '.image' \\
\text{pbimage} = 'imname + '.flux' \\
\text{pbcorimage} = 'imname + '.pbcor'
\]
outfile = pbcorimage
expr="'"+clnimage+"'/"'+pbimage+"'["'+pbimage+"']>0.1"

immath()

Note that we did not use a `minpb` when we cleaned, so we use the trick above to effectively set a
cutoff in the primary beam `.flux` image of 0.1.

For more on LEL strings, see AIPS++ Note 223

http://aips2.nrao.edu/docs/notes/223/223.html

or in §6.1.3 above.

### 6.5.1.4 Spectral analysis

One can make an integrated 1-d spectrum over the whole image by rebinning (integrating) over the
two coordinate axes in a specified region. For example, using the NGC5921 image cube (with 46
channels):

```python
immath(outfile="ngc5921.demo.spectrum.all",mode="evalexpr",
       expr="rebin('ngc5921.demo.clean.image',[256,256,1,1])")
```

The resulting image has shape `[1,1,1,46]` as desired. You can view this with the `viewer` and will
see a 1-D spectrum.

One can also do this with a box:

```python
immath(outfile="ngc5921.demo.spectrum.box",mode="evalexpr",
       expr="rebin('ngc5921.demo.clean.image',[256,256,1,1])",box="118,118,141,141")
```

**BETA ALERT:** One cannot specify a `region` without it collapsing the channel axis (even when
told to use all axes or channels).

**BETA ALERT:** The following uses the toolkit (§6.12). You can make an ascii file containing
only the values (no other info though):

```python
ia.open('ngc5921.demo.spectrum.all')
ia.toASCII('ngc5921.demo.spectrum.all.ascii')
```

You can also extract to a record inside Python:

```python
myspec = ia.torecord()
```

which you can then manipulate in Python.
6.5.2 Using masks in \texttt{immath}

The \texttt{mask} parameter is used inside \texttt{immath} to apply a mask to all the images used in \texttt{expr} before calculations are done (if you are curious, it uses the \texttt{ia.subimage} tool method to make virtual images that are then input in the LEL to the \texttt{ia.imagecalc} method).

For example, let's assume that we have made a single channel image using \texttt{clean} for the NGC5921 data (see Appendix F.1).

\begin{verbatim}
  default('clean')
  vis = 'ngc5921.ms.contsub'
  imagename = 'ngc5921.chan21.clean'
  mode = 'channel'
    nchan = 1
    start = 21
    step = 1
  field = '0'
  spw = '',
  imsize = [256,256]
  cell = [15.,15.]
  alg = 'clark'
  gain = 0.1
  niter = 6000
  threshold=8.0
  weighting = 'briggs'
    rmode = 'norm'
    robust = 0.5
  mask = '',
  clean()

  There is now a file 'ngc5921.chan21.clean.cleanbox.mask' that is an image with values 1.0 inside the cleanbox region and 0.0 outside.

  We can use this to mask the clean image:

  default('immath')
  expr='"ngc5921.chan21.clean.image"'
  mask='"ngc5921.chan21.clean.cleanbox.mask">0.5'
  outfile='ngc5921.chan21.clean.imasked'
  go

  Note that there are also pixel masks that can be contained in each image. These are Boolean masks, and are implicitly used in the calculation for each image in \texttt{expr}. If you want to use the mask in a different image not in \texttt{expr}, try it in \texttt{mask}:
\end{verbatim}
# First make a pixel mask inside ngc5921.chan21.clean.cleanbox.mask
ia.open('ngc5921.chan21.clean.cleanbox.mask')
ia.calcmask('"ngc5921.chan21.clean.cleanbox.mask">0.5')
ia.summary()
ia.close()

# There is now a 'mask0' mask in this image as reported by the summary

# Now apply this pixel mask in immath
default('immath')
expr='"ngc5921.chan21.clean.image",
mask='mask(ngc5921.chan21.clean.cleanbox.mask)'
outfile='ngc5921.chan21.clean.imasked1'
go

Note that nominally the axes of the mask must be congruent to the axes of the images in expr. However, one exception is that the image in mask can have fewer axes (but not axes that exist but are of the wrong lengths). In this case immath will extend the missing axes to cover the range in the images in expr. Thus, you can apply a mask made from a single channel to a whole cube.

# drop degenerate stokes and freq axes from
# ngc5921.chan21.clean.cleanbox.mask
ia.open('ngc5921.chan21.clean.cleanbox.mask')
im2 = ia.subimage(outfile='ngc5921.chan21.mymask',dropdeg=True)
im2.summary()
im2.close()

# ngc5921.chan21.mymask has only RA and Dec axes

# Now apply this mask to the whole cube
default('immath')
expr='"ngc5921.clean.image",
mask='"ngc5921.chan21.mymask">0.5'
outfile='ngc5921.cube.imasked'
go

For more on masks as used in LEL, see

http://aips2.nrao.edu/docs/notes/223/223.html

or in §6.1.4 above.

### 6.6 Computing the Moments of an Image Cube (immoments)

For spectral line datasets, the output of the imaging process is an image cube, with a frequency or velocity channel axis in addition to the two sky coordinate axes. This can be most easily thought of as a series of image planes stacked along the spectral dimension.
A useful product to compute is to collapse the cube into a *moment* image by taking a linear combination of the individual planes:

\[ M_m(x_i, y_i) = \sum_k w_m(x_i, y_i, v_k) I(x_i, y_i, v_k) \]  

(6.1)

for pixel \( i \) and channel \( k \) in the cube \( I \). There are a number of choices to form the \( m \) moment, usually approximating some polynomial expansion of the intensity distribution over velocity mean or sum, gradient, dispersion, skew, kurtosis, etc.). There are other possibilities (other than a weighted sum) for calculating the image, such as median filtering, finding minima or maxima along the spectral axis, or absolute mean deviations. And the axis along which to do these calculation need not be the spectral axis (ie. do moments along Dec for a RA-Velocity image). We will treat all of these as generalized instances of a “moment” map.

The **immoments** task will compute basic moment images from a cube. The default inputs are:

```
# immoments :: Compute moments of an image cube:
imagename = '' # Input image name
moments = [0] # List of moments you would like to compute
axis = 'spectral' # The moment axis: ra, dec, lat, long, spectral, or stokes
region = '' # Image Region. Use viewer
box = '' # Select one or more box regions
chans = '' # Select the channel(spectral) range
stokes = '' # Stokes params to image (I,IV,IQU,IQUV)
mask = '' # mask used for selecting the area of the image to calculate the moments on
includepix = -1 # Range of pixel values to include
excludepix = -1 # Range of pixel values to exclude
outfile = '' # Output image file name (or root for multiple moments)
async = False # If true the taskname must be started using immoments(...)```

This task will operate on the input file given by `imagename` and produce a new image or set of images based on the name given in `outfile`.

The **moments** parameter chooses which moments are calculated. The choices for the operation mode are:

- `moments=-1` - mean value of the spectrum
- `moments=0` - integrated value of the spectrum
- `moments=1` - intensity weighted coordinate; traditionally used to get 'velocity fields'
- `moments=2` - intensity weighted dispersion of the coordinate; traditionally used to get 'velocity dispersion'
- `moments=3` - median of I
- `moments=4` - median coordinate
- `moments=5` - standard deviation about the mean of the spectrum
- `moments=6` - root mean square of the spectrum
- `moments=7` - absolute mean deviation of the spectrum
- `moments=8` - maximum value of the spectrum
- `moments=9` - coordinate of the maximum value of the spectrum
- `moments=10` - minimum value of the spectrum
- `moments=11` - coordinate of the minimum value of the spectrum
The meaning of these is described in the CASA Reference Manual:

http://casa.nrao.edu/docs/casaref/image.moments.html

If a single moment is chosen, the \texttt{outfile} specifies the exact name of the output image. If multiple \texttt{moments} are chosen, then \texttt{outfile} will be used as the root of the output filenames, which will get different suffixes for each moment. For example, if \texttt{moments=[0,1]} and \texttt{outfile='ngc5921.usecase.moments'} then the output image names will be 'ngc5921.usecase.moments.integrated' and 'ngc5921.usecase.moments.weighted coord' respectively.

The \texttt{axis} parameter sets the axis along which the moment is “collapsed” or calculated. Choices are: \texttt{'ra'}, \texttt{'dec'}, \texttt{'lat'}, \texttt{'long'}, \texttt{'spectral'}, or \texttt{'stokes'}. A standard moment-0 or moment-1 image of a spectral cube would use the default choice \texttt{'spectral'}. One could make a position-velocity map by setting \texttt{'ra'} or \texttt{'dec'}.

The \texttt{includepix} and \texttt{excludepix} parameters are used to set ranges for the inclusion and exclusion of pixels based on values. For example, \texttt{includepix=[0.05,100.0]} will include pixels with values from 50 mJy to 1000 Jy, and \texttt{excludepix=[100.0,1000.0]} will exclude pixels with values from 100 to 1000 Jy.

\subsection{Hints for using (immoments)}

In order to make an unbiased moment-0 image, do not put in any thresholding using \texttt{includepix} or \texttt{excludepix}. This is so that the (presumably) zero-mean noise fluctuations in off-line parts of the image cube will cancel out. If your image has large biases, like a pronounced clean bowl due to missing large-scale flux, then your moment-0 image will be biased also. It will be difficult to alleviate this with a threshold, but you can try.

To make a usable moment-1 (or higher) image, on the other hand, it is critical to set a reasonable threshold to exclude noise from being added to the moment maps. Something like a few times the rms noise level in the usable planes seems to work (put into \texttt{includepix} or \texttt{excludepix} as needed. Also use \texttt{chans} to ignore channels with bad data.

\subsection{Examples using (immoments)}

For example, using the NGC5921 example (§F.1):

\begin{verbatim}
default('immoments')

imagename = 'ngc5921.demo.cleanimg.image'

# Do first and second moments
moments = [0,1]

# Need to mask out noisy pixels, currently done
# using hard global limits
\end{verbatim}
excludepix = [-100, 0.009]

# Include all channels
chans = ''

# Output root name
outfile = 'ngc5921.demo.moments'

immoments()

# It will have made the images:
# --------------------------------------
# ngc5921.demo.moments.integrated
# ngc5921.demo.moments.weighted_coord

Other examples of NGC2403 (a moment zero image of a VLA line dataset) and NGC4826 (a moment one image of a BIMA CO line dataset) are shown in Figure 6.1.

Figure 6.1: NGC2403 VLA moment zero (left) and NGC4826 BIMA moment one (right) images as shown in the viewer.

BETA ALERT: We are working on improving the thresholding of planes beyond the global cutoffs in includepix and excludepix.

6.7 Computing image statistics (imstat)

The imstat task will calculate statistics on a region of an image, and return the results as a return value in a Python dictionary.
The inputs are:

```python
# imstat :: Displays statistical information on an image or image region
imagename = '' # Name of the input image
region = '' # Image Region or name. Use Viewer
box = '' # Select one or more box regions
chans = '' # Select the channel(spectral) range
stokes = '' # Stokes params to image (I,IV,IQU,IQUV)
async = False
```

Area selection using `box` and `region` is detailed in §6.1.1 and §6.1.5 respectively.

Plane selection is controlled by `chans` and `stokes`. See §6.1.2 for details on plane selection.

**BETA ALERT:** As with `imcontsub`, if the image is missing one or more of the stokes and spectral axes, then `imstat` will fail. See the discussion of the workaround for this in §6.3.

### 6.7.1 Using the task return value

The contents of the return value of `imstat` are in a Python dictionary of key-value sets. For example,

```python
xstat = imstat()
```

will assign this to the Python variable `xstat`. **BETA ALERT:** The return of the statistics as a return value (and not a global variable) is new to Patch 2.0.

The keys for `xstat` are then:

```
KEYS
blc     - absolute PIXEL coordinate of the bottom left corner of
          the bounding box surrounding the selected region
blcf    - Same as blc, but uses WORLD coordinates instead of pixels
trc     - the absolute PIXEL coordinate of the top right corner
          of the bounding box surrounding the selected region
trcf    - Same as trc, but uses WORLD coordinates instead of pixels
flux    - the integrated flux density if the beam is defined and
          the if brightness units are $Jy/beam$

npts    - the number of unmasked points used
max     - the maximum pixel value
min     - minimum pixel value
maxpos  - absolute PIXEL coordinate of maximum pixel value

maxposf - Same as maxpos, but uses WORLD coordinates instead of pixels

minpos  - absolute pixel coordinate of minimum pixel value

minposf - Same as minpos, but uses WORLD coordinates instead of pixels

sum     - the sum of the pixel values: $\sum I_i$

sumsq   - the sum of the squares of the pixel values: $\sum I_i^2$

mean    - the mean of pixel values:
          \[ \operatorname{ar\{I\}} = \frac{\sum I_i}{n} \]
CHAPTER 6. IMAGE ANALYSIS

sigma - the standard deviation about the mean:
\[ \sigma^2 = \frac{\sum I_i - \text{ar(I)}^2}{n-1} \]

rms - the root mean square:
\[ \sqrt{\frac{\sum I_i^2}{n}} \]

median - the median pixel value (if robust=T)
medabsdevmed - the median of the absolute deviations from the median (if robust=T)
quartile - the inter-quartile range (if robust=T). Find the points which are 25% largest and 75% largest (the median is 50% largest), find their difference and divide that difference by 2.

For example, an imstat call might be

```python
default('imstat')
imagename = 'ngc5921.usecase.clean.image'  # The NGC5921 image cube
box = '108,108,148,148'  # 20 pixels around the center
chans = '21'  # channel 21
xstat = imstat()
```

In the terminal window, imstat reports:

Statistics on ngc5921.usecase.clean.image

Region ---
- bottom-left corner (pixel) [blc]: [108, 108, 0, 21]
- top-right corner (pixel) [trc]: [148, 148, 0, 21]
- bottom-left corner (world) [blcf]: 15:22:20.076, +04:58.59.981, I, 1.41332e+09Hz
- top-right corner (world) [trcf]: 15:21:39.919, +05:08.59.981, I, 1.41332e+09Hz

Values --
- flux [flux]: 0.111799236126
- number of points [npts]: 1681.0
- maximum value [max]: 0.029451508075
- minimum value [min]: -0.00512453464419
- position of max value (pixel) [maxpos]: [124, 131, 0, 21]
- position of min value (pixel) [minpos]: [142, 110, 0, 21]
- position of max value (world) [maxposf]: 15:22:04.016, +05:04.44.999, I, 1.41332e+09Hz
- position of min value (world) [minposf]: 15:21:45.947, +04:59.29.990, I, 1.41332e+09Hz
- Sum of pixel values [sum]: 1.32267159822
- Sum of squared pixel values [sumsq]: 0.0284534543692

Statistics ---
- Mean of the pixel values [mean]: 0.000786836167885
- Standard deviation of the Mean [sigma]: 0.00403944306904
- Root mean square [rms]: 0.00411418313161
- Median of the pixel values [median]: 0.000137259965413
- Median of the deviations [medabsdevmed]: 0.00152346317191
- Quartile [quartile]: 0.00305395200849
The return value in `xstat` is

CASA <152>: xstat
   Out[152]:
   {'blc': array([108, 108, 0, 21]),
    'blcf': '15:22:20.076, +04.58.59.981, I, 1.41332e+09Hz',
    'flux': array([0.11179924]),
    'max': array([0.02945151]),
    'maxpos': array([124, 131, 0, 21]),
    'maxposf': '15:22:04.016, +05.04.44.999, I, 1.41332e+09Hz',
    'mean': array([0.00078684]),
    'medabsdevmed': array([0.00152346]),
    'median': array([0.00013726]),
    'min': array([-0.00612453]),
    'minpos': array([142, 110, 0, 21]),
    'minposf': '15:21:45.947, +04.59.29.990, I, 1.41332e+09Hz',
    'npts': array([1681.]),
    'quartile': array([0.00305395]),
    'rms': array([0.00411418]),
    'sigma': array([0.00403944]),
    'sum': array([1.3226716]),
    'sumsq': array([0.02845345]),
    'trc': array([148, 148, 0, 21]),
    'trcf': '15:21:39.919, +05.08.59.981, I, 1.41332e+09Hz'}

**BETA ALERT:** The return dictionary currently includes NumPy array values, which have to be accessed by an array index to get the array value.

To access these dictionary elements, use the standard Python dictionary syntax, e.g.

\[ xstat[\text{<key string>}[\text{<array index>}] \]

For example, to extract the standard deviation as a number

\[
\text{mystddev} = xstat[\text{'sigma']}[0]
\]

### 6.7.2 Examples using `imstat`

We give a few examples of the use of `imstat`, in particular to extract the information from the return value.

Select a two box region:

```python
# box 1, bottom-left coord is 2,3 and top-right coord is 14,15
# box 2, bottom-left coord is 30,31 and top-right coord is 42,43
xstat = imstat( 'myImage', box='2,3,14,15;30,31,42,43' )
```

Select the same two box regions but only channels 4 and 5:

```python
# box 1, bottom-left coord is 2,3 and top-right coord is 14,15
# box 2, bottom-left coord is 30,31 and top-right coord is 42,43
xstat = imstat( 'myImage', box='2,3,14,15;30,31,42,43', channel='4,5' )
```
Select all channels greater than 20 as well as channel 0, and print the mean and standard deviation:

```python
xstat = imstat( 'myImage', chans='>20;0' )
print "Mean is: ", xstat['mean'][0], " s.d. ", xstat['sigma'][0]
```

Find statistical information for the Q stokes value only then the I stokes values only, and print out the statistical values that we are interested in:

```python
xstat = imstat( 'myImage', stokes='Q' )
s1=xstat
imstat( 'myImage', stokes='I' )
s2=xstat
print " | MIN | MAX | MEAN"
print " Q | ",s1['min'][0]," | ",s1['max'][0]," | ",, | ",s1['mean'][0]
print " I | ",s2['min'][0]," | ",s2['max'][0]," | ",, | ",s2['mean'][0]
```

### 6.8 Extracting data from an image (imval)

The `imval` task will extract the values of the data and mask from a specified region of an image and place in the task return value as a Python dictionary.

The inputs are:

```python
# imval :: Get the data value(s) and/or mask value in an image.
imagename = '' # Name of the input image
region = '' # Image Region. Use viewer
box = '' # Select one or more box regions
chans = '' # Select the channel(spectral) range
stokes = '' # Stokes params to image (I,IV,IQU,IQUV)
async = False
```

Area selection using `box` and `region` is detailed in §6.1.1 and §6.1.5 respectively. By default, `box=''` will extract the image information at the reference pixel on the direction axes.

Plane selection is controlled by `chans` and `stokes`. See §6.1.2 for details on plane selection. By default, `chans=''` and `stokes=''` will extract the image information in all channels and Stokes planes.

For instance,

```python
xval = imval('myimage', box='144,144', stokes='I')
```

will extract the Stokes I value or spectrum at pixel 144,144, while
\[
xval = \text{imval('myimage', box='134,134.154,154', stokes='I')}
\]

will extract a 21 by 21 pixel region.

Extractions are returned in NumPy arrays in the return value dictionary, plus some extra elements describing the axes and selection:

CASA <2>: \[xval = \text{imval('ngc5921.demo.moments.integrated')}\]

CASA <3>: \[xval\]

\[
\text{Out}[3]:
\{'axes': [[0, 'Right Ascension'], [1, 'Declination'], [3, 'Frequency'], [2, 'Stokes']],
'blc': [128, 128, 0, 0],
'data': array([ 0.89667124]),
'mask': array([ True], dtype=bool),
'trc': [128, 128, 0, 0],
'unit': 'Jy/beam.km/s'}
\]

extracts the reference pixel value in this 1-plane image. Note that the 'data' and 'mask' elements are NumPy arrays, not Python lists.

To extract a spectrum from a cube:

CASA <8>: \[xval = \text{imval('ngc5921.demo.clean.image', box='125,125')}\]

CASA <9>: \[xval\]

\[
\text{Out}[9]:
\{'axes': [[0, 'Right Ascension'], [1, 'Declination'], [3, 'Frequency'], [2, 'Stokes']],
'blc': [125, 125, 0, 0],
'data': array([[ 0.45784932e-04,  0.23988660e-04,  0.12798368e-04,  0.80087778e-05,
               0.46785258e-05,  0.25791880e-05,  0.13083751e-05,  0.74893219e-06,
               0.41671807e-06,  0.22479626e-06,  0.12353766e-06,  0.71739839e-07,
               0.39346267e-07,  0.21629355e-07,  0.11874677e-07,  0.65393184e-08,
               0.35598087e-08,  0.19325766e-08,  0.10791204e-08,  0.58146456e-09,
               0.32092991e-09,  0.17081535e-09,  0.94170006e-10,  0.51585181e-10]],
'unit': 'Jy/beam.km/s'}
\]
CHAPTER 6. IMAGE ANALYSIS

To extract a region from the plane of a cube:

CASA <13>: xval = imval('ngc5921.demo.clean.image', box='126,128,130,129', chans='23')

CASA <14>: xval

Out[14]:
{'axes': [[0, 'Right Ascension'],
          [1, 'Declination'],
          [3, 'Frequency'],
          [2, 'Stokes']],
 'blc': [126, 128, 0, 23],
 'data': array([[ 0.00938627, 0.01487772],
                [ 0.00955847, 0.01688832],
                [ 0.00696965, 0.01501907],
                [ 0.00460964, 0.01220793],
                [ 0.00358087, 0.00990202]],
 'mask': array([[ True, True],
               [ True, True],
               [ True, True],
               [ True, True],
               [ True, True]], dtype=bool),
 'trc': [130, 129, 0, 23],
 'unit': 'Jy/beam'}

CASA <15>: print xval['data'][0][1]
0.0148777160794

In this example, a rectangular box was extracted, and you can see the order in the array and how to address specific elements.

6.9 Regridding an Image (imregrid)

It is occasionally necessary to regrid an image onto a new coordinate system. The imregrid task will regrid one image onto the coordinate system of another, creating an output image. In this task, the user need only specify the names of the input, template, and output images.

Inside the Toolkit:
More complex coordinate system and image regridding operation can be carried out in the toolkit. The coordsys (cs) tool and the ia.regrid method are the relevant components.
If the user needs to do more complex operations, such as regridding an image onto an arbitrary (but known) coordinate system, changing from Equatorial to Galactic coordinates, or precessing Equinoxes, the CASA toolkit can be used (see sidebox). Some of these facilities will eventually be provided in task form.

The default inputs are:

```python
# imregrid :: regrid an image onto a template image
imagename = '' # Name of input image
template = '' # Name of reference image
output = '' # Name of output regridded image
async = False
```

The output image will have the data in `imagename` regridded onto the coordinate system of `template` image.

**BETA ALERT:** The `imregrid` task is currently under test against similar AIPS tasks and we are looking to improve its performance. Future releases will enable regridding without the need for a template image.

### 6.10 Image Convolution (`imsmooth`)

The default inputs are:

```python
# imsmooth :: Smooth an image or portion of an image
imagename = '' # Name of the input image
kernel = 'boxcar' # Type of kernel to use: gaussian or boxcar.
region = '' # Image Region or name. Use viewer
box = '' # Select one or more box regions
chans = '' # Select the channel(spectral) range
stokes = '' # Stokes params to image (I,IV,IQU,UV)
mask = '' # mask used for selecting the area of the image to smooth
outfile = '' # Output, smoothed, image file name
async = False
```

### 6.11 Image Import/Export to FITS

These tasks will allow you to write your CASA image to a FITS file that other packages can read, and to import existing FITS files into CASA as an image.
6.11.1 FITS Image Export (exportfits)

To export your images to fits format use the exportfits task. The inputs are:

```python
# exportfits :: Convert a CASA image to a FITS file
imagename = '' # Name of input CASA image
fitsimage = '' # Name of output image FITS file
velocity = False # Use velocity (rather than frequency) as spectral axis
optical = False # Use the optical (rather than radio) velocity convention
bitpix = -32 # Bits per pixel
minpix = 0 # Minimum pixel value
maxpix = 0 # Maximum pixel value
overwrite = False # Overwrite pre-existing imagename
dropstokes = False # Drop the Stokes axis?
stokeslast = True # Put Stokes axis last in header?
async = True # If true the taskname must be started using exportfits(...)  
```

The dropstokes or stokeslast parameter may be needed to make the FITS image compatible with an external application.

For example,

```python
exportfits('ngc5921.usecase.clean.image','ngc5921.usecase.image.fits')
```

**BETA ALERT:** Setting async=True is recommended because there is a flaw in the Beta version of the FITS classes that will cause subsequent FITS import (importfits or importuvfits) after an export to fail. Using asynchronous export will circumvent this by forcing the creation and use of a new tool object rather than using default one.

6.11.2 FITS Image Import (importfits)

You can also use the importfits task to import a FITS image into CASA image table format. Note, the CASA viewer can read fits images so you don’t need to do this if you just want to look at the image. The inputs for importfits are:

```python
# importfits :: Convert an image FITS file into a CASA image:
fitsimage = '' # Name of input image FITS file
imagename = '' # Name of output CASA image
whichrep = 0 # Which coordinate representation (if multiple)
whichhdu = 0 # Which image (if multiple)
zeroblanks = True # If blanked fill with zeros (not NaNs)
overwrite = False # Overwrite pre-existing imagename
async = False # if True run in the background, prompt is freed
```

For example, we can read the above image back in

```python
importfits('ngc5921.usecase.image.fits','ngc5921.usecase.image.im')
```
6.12 Using the CASA Toolkit for Image Analysis

Although this cookbook is aimed at general users employing the tasks, we include here a more detailed description of doing image analysis in the CASA toolkit. This is because there are currently only a few tasks geared towards image analysis, as well as due to the breadth of possible manipulations that the toolkit allows that more sophisticated users will appreciate.

To see a list of the ia methods available, use the CASA help command:

CASA <1>: help ia
--------- help(ia)
Help on image object:

class image(_builtin_.object)
    image object

    Methods defined here:

    __init__(...)
    x.__init__(...) initializes x; see x.__class__.__doc__ for signature

    __str__(...)
    x.__str__() <==> str(x)

    adddegaxes(...)
    Add degenerate axes of the specified type to the image' :
    outfile
    direction = false
    spectral = false
    stokes
    linear = false
    tabular = false
    overwrite = false
    ----------------------------------------

    addnoise(...)  

    ...

    unlock(...)
    Release any lock on the image' :
    ----------------------------------------

    ----------------------------------------

Data and other attributes defined here:
A common use of the `ia` tool is to do region statistics on an image. The `imhead` task has `mode='stats'` to do this quickly over the entire image cube. The tool can do this on specific planes or sub-regions. For example, in the Jupiter 6cm example script (§ [F.2], the `ia` tool is used to get on-source and off-source statistics for regression:

```python
# The variable `clnimage` points to the clean image name
```
CHAPTER 6. IMAGE ANALYSIS

# Pull the max and rms from the clean image
ia.open(clnimage)
on_statistics=ia.statistics()
thistest_immax=on_statistics['max'][0]
oldtest_immax = 1.07732224464
print ' Clean image ON-SRC max should be ',oldtest_immax
print ' Found : Max in image = ',thistest_immax
diff_immax = abs((oldtest_immax-thistest_immax)/oldtest_immax)
print ' Difference (fractional) = ',diff_immax

print ''
# Now do stats in the lower right corner of the image
box = ia.setboxregion([0.75,0.00],[1.00,0.25],frac=true)
off_statistics=ia.statistics(region=box)
thistest_imrms=off_statistics['rms'][0]
oldtest_imrms = 0.0010449
print ' Clean image OFF-SRC rms should be ',oldtest_imrms
print ' Found : rms in image = ',thistest_imrms
diff_imrms = abs((oldtest_imrms-thistest_imrms)/oldtest_imrms)
print ' Difference (fractional) = ',diff_imrms

print ''
print ' Final Clean image Dynamic Range = ',thistest_immax/thistest_imrms
print ''
print ' =============== '

ia.close()

BETA ALERT:  Bad things can happen if you open some tools, like ia, in the Python command line on files and forget to close them before running scripts that use the os.system(’rm -rf <filename>) call to clean up. We are in the process of cleaning up cases like this where there can be stale handles on files that have been manually deleted, but for the meantime be warned that you might get exceptions (usually of the “SimpleOrderedMap-remove” flavor, or even Segmentation Faults and core-dumps!

6.13 Examples of CASA Image Analysis

See the scripts provided in Appendix F for examples of data and image analysis. In particular, we refer the interested user to the demonstrations for:

- NGC5921 (VLA HI) — a quick demo of basic CASA spectral line analysis
- Jupiter (VLA 6cm continuum polarimetry) — polarization image analysis
Chapter 7

Visualization With The CASA Viewer

This chapter describes how to display data with the casaviewer either as a stand-alone or through the viewer task. You can display both images and Measurement Sets.

7.1 Starting the viewer

Within the casapy environment, the viewer task can be used to display an image or MS. The inputs are:

```
# viewer :: View an image or visibility data set.

infile = '' # (Optional) Name of file to visualize.
displaytype = 'raster' # (Optional) Type of visual rendering
                      # (raster, contour, vector or marker).
                      # lel if an lel expression is given
                      # for infile (advanced).
```

Examples of starting the viewer:

```
CASA <1>: viewer()
CASA <2>: viewer('ngc5921.usecase.ms')
CASA <3>: viewer('ngc5921.usecase.clean.image')
CASA <4>: viewer('ngc5921.usecase.clean.image.rstr')
CASA <5>: viewer('ngc5921.usecase.clean.image', 'contour')
CASA <6>: viewer('"ngc5921.usecase.clean.image"^2', 'lel')
```
CHAPTER 7. VISUALIZATION WITH THE CASA VIEWER

Figure 7.1: The Viewer Display Panel (left) and Data Display Options (right) panels that appear when the viewer is called with the image cube from NGC5921 (viewer('ngc5921.usecase.clean.image')). The initial display is of the first channel of the cube.

The first of these creates an empty Viewer Display Panel (§7.2.1) and a Load Data window (§7.2.4). The second starts the viewer loaded with a Measurement Set. The third example starts the viewer with an image cube (see Figure 7.1).

Example four brings up a display panel as it was when its state was saved to the given 'restore' file (ngc5921.usecase.clean.image.rstr). This includes the data displayed as well as options and viewer settings. (See §7.2.2 Saving and Restoring Viewer State).

Examples five and six are less common cases, which make use of the second parameter (displaytype). Example five displays the image in contour form. Example six uses 'Lattice (Image) Expression Language' to display the square of the image data.

NOTE: the viewer task now determines file types (images, MSs, restore files) automatically. It is no longer necessary to specify filetype='ms' explicitly.
7.1.1 Running the CASA viewer outside casapy

`casaviewer` is the name of the stand-alone viewer application that is available with a CASA installation. From the operating system prompt, the following commands are equivalent to the `casapy` task commands given previously:

```bash
casaviewer &
casaviewer ms_filename &
casaviewer image_filename &
casaviewer restore_filename &
```
7.2 The viewer GUI

The CASA viewer application consists of a number of graphical user interface (GUI) windows that respond to mouse and keyboard input. Here we describe the Viewer Display Panel (§7.2.1) and the Load Data window (§7.2.4). They are used for both image and MS viewing. Several other windows are context-specific and are described in the sections on viewing images (§7.3) and Measurement Sets (§7.4).

7.2.1 The Viewer Display Panel

The Viewer Display Panel is the window that actually displays the image or MS. This is shown in the left panels of Figures 7.1 and 7.2. Note that this panel is the same whether an image or MS is being displayed.

At the top of the Viewer Display Panel are the menus:

- **Data**
  - Open — choose a data file to load and display
  - Register — select/de-select the (previously-loaded) data file(s) which should display right now (menu expands to the right showing all loaded data)
  - Close — close (unload) selected data file (menu expands to the right)
  - Adjust — open the Data Display Options ('Adjust') panel
  - Print — print the displayed image
  - Save Panel State — to a 'restore' file (xml format)
  - Restore Panel State — from a restore file
  - Close Panel — close the Viewer Display Panel (will exit if this is the last display panel open)
  - Quit Viewer — close all display panels and exit

- **Display Panel**
  - New Panel — create another Viewer Display Panel (cleared)
  - Panel Options — open the Display Panel's options window
  - Save Panel State
  - Restore Panel State
  - Print — print displayed image
CHAPTER 7. VISUALIZATION WITH THE CASA VIEWER

- **Close Panel** — close the Viewer Display Panel (will exit if this is the last display panel open)

- **Tools**
  - **Annotations** — not yet available (greyed out)
  - **Spectral Profile** — plot frequency/velocity profile of point or region of image
  - **Region Manager** — save regions and control their extent

- **View**
  - **Main Toolbar** — show/hide top row of icons
  - **Mouse Toolbar** — show/hide second row of mouse-button action selection icons
  - **Animator** — show/hide tapedeck control panel
  - **Position Tracking** — show/hide bottom position tracking report box

Below this is the **Main Toolbar** (Figure 7.3), the top row of icons for fast access to some of these menu items:

- **folder** ([Data:Open shortcut]) — show the Load Data panel
- **wrench** ([Data:Adjust shortcut]) — show the Data Display Options ('Adjust') panel
- **panels** ([Data:Register shortcut]) — show the menu of loaded data
- **delete** ([Data:Close shortcut]) — closes/unloads selected data
- **new panel** ([Display Panel:New Panel])
- **panel wrench** ([Display Panel:Panel Options]) — show the Display Panel’s options window
- **save** — save panel state to a 'restore' file
- **restore** — restore panel state from a restore file
- **region save** ([Tools:Region Manager]) — save/control regions.
  (Note: some of these newer buttons do not appear in older figures of this document).
- **print** ([Display Panel:Print]) — print data
- **magnifier box** — Zoom out all the way
- **magnifier plus** — Zoom in (by a factor of 2)
- **magnifier minus** — Zoom out (by a factor of 2)
CHAPTER 7. VISUALIZATION WITH THE CASA VIEWER

261

Figure 7.3: The display panel’s **Main Toolbar** appears directly below the menus and contains ‘shortcut’ buttons for most of the frequently-used menu items.

Figure 7.4: The **Mouse Tool Bar** allows you to assign separate mouse buttons to tools you control with the mouse within the image display area. Initially, zooming, color adjustment, and rectangular regions are assigned to the left, middle and right mouse buttons, respectively.

Below this are the eight **Mouse Tool** buttons (Figure [7.4]). These allow assignment of each of the three mouse buttons to a different operation on the display area. Clicking a mouse tool icon will re-assign the mouse button that was clicked to that tool. The icons show which mouse button is currently assigned to which tool.

The ‘escape’ key can be used to cancel any mouse tool operation that was begun but not completed, and to erase any tool showing in the display area.

- **Zooming (magnifying glass icon):** To zoom into a selected area, press the Zoom tool’s mouse button (the *left* button by default) on one corner of the desired rectangle and drag to the desired opposite corner. Once the button is released, the zoom rectangle can still be moved or resized by dragging. To complete the zoom, double-click inside the selected rectangle (double-clicking *outside* it will zoom *out* instead).

- **Panning (hand icon):** Press the tool’s mouse button on a point you wish to move, drag it to the position where you want it moved, and release. *Note:* The arrow keys, Page Up, Page Down, Home and End keys can also be used to scroll through your data any time you are zoomed in. (Click on the main display area first, to be sure the keyboard is ‘focused’ there).

- **Stretch-shift colormap fiddling (crossed arrows):** This is usually the handiest color adjustment; it is assigned to the *middle* mouse button by default.

- **Brightness-contrast colormap fiddling (light/dark sun)**

- **Positioning (bombsight):** This tool can place a ‘crosshair’ marker on the display to select a position. It is used to flag Measurement Set data or to select an image position for spectral profiles. Click on the desired position with the tool’s mouse button to place the crosshair; once placed you can drag it to other locations. Double-click is not needed for this tool. See §7.2.3 for more detail.
• **Rectangle and Polygon region drawing:** The rectangle region tool is assigned to the right mouse button by default. As with the zoom tool, a rectangle region is generated by dragging with the assigned mouse button; the selection is confirmed by double-clicking within the rectangle. Polygon regions are created by clicking the assigned mouse button at the desired vertices, clicking the final location twice to finish. Once created, a polygon can be moved by dragging from inside, or reshaped by dragging the handles at the vertices. Double-click inside to confirm region selection. See §7.2.3 for the uses of this tool.

• **Polyline drawing:** A polyline can be created by selecting this tool. It is manipulated similarly to the polygon region tool: create segments by clicking at the desired positions and then double-click to finish the line. [Uses for this tool are still to be implemented].

The main **Display Area** lies below the toolbars.

Underneath the display area is an **Animator** panel. The most prominent feature is the “tape deck” which provides movement between image planes along a selected third dimension of an image cube. This set of buttons is only enabled when a registered image reports that it has more than one plane along its ‘Z axis’. In the most common case, the animator selects the frequency channel. From left to right, the tape deck controls allow the user to:

- **rewind** to the start of the sequence (i.e., the first plane)
- **step backwards** by one plane
- **play backwards**, or repetitively step backwards
- **stop** any current play
- **play forward**, or repetitively step forward
- **step forward** by one plane
- **fast forward** to the end of the sequence

To the right of the tape deck is an editable text box indicating the current frame (channel) number and a label showing the total number of frames. Below that is a slider for controlling the (nominal) animation speed. To the right is a 'Full/Compact' toggle. In 'Full' mode (the default), a slider controlling frame number and a 'Blink mode' control are also available.

'Blink' mode is useful when more than one raster image is registered. In that mode, the tapedeck controls which image is displayed at the moment rather than the particular image plane (set that in 'Normal' mode first). The registered images must cover the same portion of the sky and use the same coordinate projection.

**Note:** In 'Normal' mode, it is advisable to have only ONE raster image registered at a time, to avoid confusion. Unregister (or close) the others.

At the bottom of the Display Panel is the **Position Tracking** panel. As the mouse moves over the main display, this panel shows information such as flux density, position (e.g. RA and Dec), Stokes,
and frequency (or velocity), for the point currently under the cursor. Each registered image/MS displays its own tracking information. Tracking can be ‘frozen’ (and unfrozen again) with the space bar. (Click on the main display area first, to be sure the keyboard is ‘focused’ there).

The Animator or Tracking panels can be hidden or detached (and later re-attached) by using the boxes at upper right of the panels; this is useful for increasing the size of the display area. (Use the ‘View’ menu to show a hidden panel again). The individual tracking areas (one for each registered image) can be hidden using the checkbox at upper left of each area.

### 7.2.2 Saving and Restoring Display Panel State

It is straightforward to save a display panel’s current state (what data is on display along with data and panel settings). Select ‘Save’ (the unadorned floppy toolbutton) and confirm the filename. It is usually advisable (but not required) to retain the file’s `.rstr` extension.

Press ‘Restore’ (the button to the right of Save) to choose a previously-created restore file. You can also select restore files from the Load Data window.

It is possible to restore MSs or images, multiple layers such as contour-over-raster, and LEL displays. You can also the save the panel state with no data loaded, to restore preferred initial settings such as overall panel size. Animation and zoom state should likewise restore themselves.

Restore is fairly forgiving about data location, and will find files located:

- in the original location recorded in the restore file
- in the current working directory (where you started the viewer)
- in the restore file’s directory
- in the original location relative to the restore file

This means that restore files will generally work if moved together with data files. The process is less forgiving if you save the display of an LEL (image) expression, however; the files must be in the locations specified in the original LEL expression. If a data file is not found, restore will attempt to proceed but results will vary.

Restore files are in ascii (xml) format, and some obvious manual edits are possible. However, these files are longer and more complex than you might imagine. Use caution, and back up restore files you want to preserve. If you make a mistake, the viewer may not recognize the file as a restore file; other unexpected results could also occur. It is usually easier and safer to make changes on the display panel and then save the restore file again.

### 7.2.3 Region Selection and Positioning

You can draw regions or select positions on the display with the mouse, once you have selected the appropriate tool(s) on the Mouse Toolbar (see above).

The Rectangle Region drawing tool currently works for the following:
• Region statistics reporting for images,
• Region spectral profiles for images, via the **Tools:Spectral Profile** menu,
• Flagging of Measurement Sets
• Creating and Saving an image region for various types of analysis (§7.3.5)
• Selecting Clean regions interactively (§5.3.5)

The **Polygon Region** drawing has the same uses, except that polygon region flagging of an MS is not supported.

The **Positioning** crosshair tool works for the last two of the above.

The **Spectral Profile** display (see §7.3.4), when active, updates on each change of the rectangle, polygon, or crosshair. Flagging with the crosshair also responds to single click or drag.

Region statistics are printed in the terminal window (not the logger) by double-clicking the completed region. The **Rectangle Region** tool's mouse button must also be double-clicked to confirm an MS flagging edit.

Here is an example of region statistics from the viewer:

```
ngc5921.usecase.clean.image-contour (Jy/beam)

<table>
<thead>
<tr>

<td>1.127</td>
</tr>
</tbody>
</table>

Flux  Med  |Dev| InterQtlRng Median Min Max
0.09526 0.009185 0.01875 0.02076 0.003584 0.04181
```

### 7.2.4 The Load Data Panel

You can use the **Load Data - Viewer** GUI to interactively choose images or MS to load into the viewer. An example of this panel is shown in Figure 7.5. This panel is accessed through the **Data:Open** menu or Open icon of the **Viewer Display Panel**. It also appears if you open the viewer without any *infile* specified.

Selecting a file on disk in the **Load Data** panel will provide options for how to display the data. Images can be displayed as:

1. Raster Image,
2. Contour Map,
3. Vector map, or
4. Marker Map.
Figure 7.5: The **Load Data - Viewer** panel that appears if you open the **viewer** without any **infile** specified, or if you use the **Data: Open** menu or Open icon. You can see the images and MS available in your current directory, and the options for loading them.

You can also enter a 'Lattice (image) Expression' in the box provided (§ 6.1.3). For example, you might enter:

'\texttt{my.clean.im} - \texttt{my.dirty.im}'

to display the difference between the two images. (The images should have the same coordinates and extents).

A MS can only be displayed as a raster.
7.2.4.1 Registered vs. Open Datasets

When you 'load' data as described above, it is first opened, and then registered on all existing Display Panels. The distinction is subtle. An 'open' dataset has been prepared in memory from disk; it may be registered (enabled for drawing) on one Display Panel and not on another. All open datasets will have a tab in the Data Options window, whether currently registered or not. On the other hand, only those datasets registered on a particular panel will show in its Tracking area.

At present, it is useful to have more than one image registered on a panel only if you are displaying a contour image over a raster image (§7.3.3) or 'blinking' between images (see Animator in §7.2.1). (In future we also hope to provide transparent overlay of raster images).

It is the user's responsibility – and highly advisable – to unregister (or close) datasets that are no longer in use, using the Register or Close toolbutton or menu. In future the viewer will attempt to aid in unregistering datasets which are not 'compatible' with a newly-loaded one (different sky area, e.g., or MS vs. image).

If you close a dataset, you must reload it from disk as described above to see it again. That can take a little time for MSs, especially. If you unregister a dataset, it is set to draw immediately when you re-register it, with its options as you have previously set them. In general, close unneeded datasets but unregister those you'll be working with again.

7.3 Viewing Images

You have several options for viewing an image. These are seen at the right of the Load Data - Viewer panel described in §7.2.4 and shown in Figure 7.6 when an image is selected. They are:

- **Raster Image** — a greyscale or color image,
- **Contour Map** — contours of intensity as a line plot,
- **Vector Map** — vectors (as in polarization) as a line plot,
- **Marker Map** — a line plot with symbols to mark positions.

The Raster Image is the default image display, and is what you get if you invoke the viewer from casapy with an image file name. In this case, you will need to use the Open menu to bring up the Load Data panel to choose a different display.

7.3.1 Viewing a raster map

A raster map of an image shows pixel intensities in a two-dimensional cross-section of gridded data with colors selected from a finite set of (normally) smooth and continuous colors, i.e., a colormap.
Figure 7.6: The Load Data - Viewer panel as it appears if you select an image. You can see all options are available to load the image as a Raster Image, Contour Map, Vector Map, or Marker Map. In this example, clicking on the Raster Image button would bring up the displays shown in Figure 7.1.

Starting the casaviewer with an image as a raster map will look something like the example in Figure 7.1.

You will see the GUI which consists of two main windows, entitled "Viewer Display Panel" and "Load Data". In the "Load Data" panel, you will see all of the viewable files in the current working directory along with their type (Image, Measurement Set, etc). After selecting a file, you are presented with the available display types (raster, contour, vector, marker) for these data. Clicking on the button Raster Map will create a display as above.

The data display can be adjusted by the user as needed. This is done through the Data Display Options panel. This window appears when you choose the Data:Adjust menu or use the wrench icon from the Main Toolbar. This also comes up by default along with the Viewer Display Panel when the data is loaded.

The Data Display Options window is shown in the right panel of Figure 7.1. It consists of a tab for each image or MS loaded, under which are a cascading series of expandable categories. For an
image, these are:

- Display axes
- Hidden axes
- Basic Settings
- Position tracking
- Axis labels
- Axis label properties
- Beam Ellipse
- Color Wedge

The Basic Settings category is expanded by default. To expand a category to show its options, click on it with the left mouse button.

### 7.3.1.1 Raster Image — Basic Settings

This roll-up is open by default. It has some commonly-used parameters that alter the way the image is displayed; three of these affect the colors used. An example of this part of the panel is shown in Figure 7.7.

![Figure 7.7: The Basic Settings category of the Data Display Options panel as it appears if you load the image as a Raster Image. This is a zoom-in for the data displayed in Figure 7.1.](image)

The options available are:
Basic Settings: Aspect ratio

This option controls the horizontal-vertical size ratio of data pixels on screen. Fixed world (the default) means that the aspect ratio of the pixels is set according to the coordinate system of the image (i.e., true to the projected sky). Fixed lattice means that data pixels will always be square on the screen. Selecting flexible allows the map to stretch independently in each direction to fill as much of the display area as possible.

Basic Settings: Pixel treatment

This option controls the precise alignment of the edge of the current 'zoom window' with the data lattice. edge (the default) means that whole data pixels are always drawn, even on the edges of the display. For most purposes, edge is recommended. center means that data pixels on the edge of the display are drawn only from their centers inwards. (Note that a data pixel’s center is considered its 'definitive' position, and corresponds to a whole number in 'data pixel' or 'lattice' coordinates).

Basic Settings: Resampling mode

This setting controls how the data are resampled to the resolution of the screen. nearest (the default) means that screen pixels are colored according to the intensity of the nearest data point, so that each data pixel is shown in a single color. bilinear applies a bilinear interpolation between data pixels to produce smoother looking images when data pixels are large on the screen. bicubic applies an even higher-order (and somewhat slower) interpolation.

Basic Settings: Data Range

You can use the entry box provided to set the minimum and maximum data values mapped to the available range of colors as a list [min, max]. For very high dynamic range images, you will probably want to enter a max less than the data maximum in order to see detail in lower brightness-level pixels. The next setting also helps very much with high dynamic range data.

Basic settings: Scaling power cycles

This option allows logarithmic scaling of data values to colormap cells.

The color for a data value is determined as follows: first, the value is clipped to lie within the data range specified above, then mapped to an index into the available colors, as described in the next paragraph. The color corresponding to this index is determined finally by the current colormap and its 'fiddling' (shift/slope) and brightness/contrast settings (see Mouse Toolbar, above). Adding a Color Wedge to your image can help clarify the effect of the various color controls.

The Scaling power cycles option controls the mapping of clipped data values to colormap indices. Set to zero (the default), a straight linear relation is used. For negative scaling values, a logarithmic mapping assigns an larger fraction of the available colors to lower data values (this is usually what you want). Setting dataMin to something around the noise level is often useful/appropriate in conjunction with a negative 'Power cycles' setting.

For positive values, an larger fraction of the colormap is used for the high data values. The actual functions are computed as follows:
See Figure 7.8 for sample curves.

![Figure 7.8: Example curves for scaling power cycles.](image)

- **Basic settings:** Colormap
  
  You can select from a variety of colormaps here. Hot Metal, Rainbow and Greyscale colormaps are the ones most commonly used.

3.1.2 Raster Image — Other Settings

Many of the other settings on the Data Options panel for raster images are self-explanatory, such as those which affect Beam ellipse drawing (only available if your image provides beam data), or the form of the Axis labeling and Position tracking information. You can also give your image a Color wedge, a key to the current mapping from data values to colors.

You can control which of your image’s axes are on the vertical and horizontal display axes and which on the animation or ‘movie’ axis, within the Display axes drop-down. You must set the X, Y and Z (animation) axes so that each shows a different image axis, in order for your choice to take effect.

If your image has a fourth axis (typically Stokes), it can be controlled by a slider within the Hidden axes drop-down.

For negative scaling values (say \(-p\)), the data is scaled linearly from the range \((dataMin - dataMax)\) to the range \((1 - 10^p)\). Then the program takes the log (base 10) of that value (arriving at a number from 0 to \(p\)) and scales that linearly to the number of available colors. Thus the data is treated as if it had \(p\) decades of range, with an equal number of colors assigned to each decade.

For positive scaling values, the inverse (exponential) functions are used. If \(p\) is the (positive) value chosen, The data value is scaled linearly to lie between 0 and \(p\), and 10 is raised to this power, yielding a value in the range \((1 - 10^p)\). Finally, that value is scaled linearly to the number of available colors.
7.3.2 Viewing a contour map

Viewing a contour image is similar to the process above. A contour map shows lines of equal data value (e.g., flux density) for the selected plane of gridded data (Figure 7.9). Contour maps are particularly useful for overlaying on raster images so that two different measurements of the same part of the sky can be shown simultaneously (§ 7.3.3).

Several Basic Settings options control the contour levels used. The contours themselves are specified by a list in the RelativeContourLevels box. These are defined relative to the two other parameters, the BaseContourLevel (which sets what 0 in the relative contour list corresponds to in the image), and the UnitContourLevel (which sets what 1 in the relative contour list corresponds to in the image). Note that negative contours are usually dashed. BETA ALERT: This scheme was adopted in 2.4.0 and is slightly different to that used in previous versions.

Figure 7.9: The Viewer Display Panel (left) and Data Display Options panel (right) after choosing Contour Map from the Load Data panel. The image shown is for channel 11 of the NGC5921 cube, selected using the Animator tape deck, and zoomed in using the tool bar icon. Note the different options in the open Basic Settings category of the Data Display Options panel.

For example, it is relatively straightforward to set fractional contours (e.g. “percent levels”), e.g.: 
RelativeContourLevels = [0.2, 0.4, 0.6, 0.8]
BaseContourLevel = 0.0
UnitContourLevel = <image max>

This maps the maximum to 1 and thus our contours are fractions of the peak.

Another example shows how to set absolute values so that the contours are given in flux density units (Jy):

RelativeContourLevels = [0.010, 0.0.020, 0.040, 0.080, 0.160, 0.320]
BaseContourLevel = 0.0
UnitContourLevel = 1.0

Here we have contours starting at 10mJy and doubling every contour.

We can also set contours in multiples of the image rms (“sigma”):

RelativeContourLevels = [-3,3,5,10,15,20]
BaseContourLevel = 0.0
UnitContourLevel = <image rms>

Here we have first contours at negative and positive 3-sigma. You can get the image rms using the `imstat` task (§ 6.7) or using the Viewer statistics tool on a region of the image (§ 7.2.3).

As a final example, not all images are of intensity, for example a moment-1 image (§ 6.6) has units of velocity. In this case, absolute contours will work fine, but by default the viewer will set fractional contours but referred to the min and max velocity:

RelativeContourLevels = [0.2, 0.4, 0.6, 0.8]
BaseContourLevel = <image min>
UnitContourLevel = <image max>

Here we have contours spaced evenly from min to max, and this is what you get by default if you load a non-intensity image (like the moment-1 image). See Figure 7.10 for an example of this.

### 7.3.3 Overlay contours on a raster map

Contours of either a second data set or the same data set can be used for comparison or to enhance visualization of the data. The Data Options Panel will have multiple tabs which allow adjusting each overlay individually (Note tabs along the top). **Beware:** it’s easy to forget which tab is active! Also note that axis labeling is controlled by the first-registered image overlay that has labeling turned on (whether raster or contour), so make label adjustments within that tab.

To add a Contour overlay, open the **Load Data** panel (Use the **Data** menu or click on the Folder icon), select the data set and select **Contour**. See Figure 7.10 for an example using NGC5921.
7.3.4 Spectral Profile Plotting

From the Tools menu, the Spectral Profile plotting tool can be selected. This will pop up a new Image Profile window containing an x-y plot of the intensity versus spectral axis (usually velocity). You can then select a region with the Rectangle or Polygon Region drawing tools, or pinpoint a position using the Crosshair tool. The profile for the region or position selected will then appear in the Image Profile window. This profile will update in real time to track changes to the region or crosshair, which can be moved by click-dragging the mouse. See Figure 7.11.

7.3.5 Managing and Saving Regions

To save a region of an image you have on display, first open the Region Manager window (the Tools:Region Manager menu item, or the corresponding toolbutton). A window will appear as in Figure 7.12.
Figure 7.11: The **Image Profile** panel that appears if you use the **Tools:Spectral Profile** menu, and then use the rectangle or polygon tool to select a region in the image. You can also use the crosshair to get the profile at a single position in the image. The profile will change to track movements of the region or crosshair if moved by dragging with the mouse.

Under **Region Extent**, choose whether you want your region to be confined to the viewed plane only, or to extend over all channels or all image planes.

Then trace out your region on the display panel using the rectangle or polygon region mouse tools (§ 7.2.1 § 7.2.3), and confirm by double-clicking inside the region. Figure 7.13 shows an image region selected with the polygon tool.

**Note:** The extent of the region is determined by the extent button in effect when the region is defined, not when it is saved. Therefore it is important to select the extent **before** double-clicking the region with the mouse. If you neglected to do this, you can just double-click again within the region after you select the extent and before saving.

Make any desired adjustments to the offered pathname and press **Save Last region** to save the region to a file. The example Casa commands below illustrate usage of such files.
reg = rg.fromfiletorecord( "my.im.rgn" )
ia.open( "my.im" )
ria.statistics( region=reg )

**BETA ALERT:** Visual region management is incomplete. Very soon, the region will be placed inside the image file rather than stored separately. Compound regions with iterative additions/deletions and better visual feedback will also be provided.

Note that the current Region Extent choice also affects the image points used in computing statistics (§ 7.2.3).

### 7.3.6 Adjusting Canvas Parameters/Multi-panel displays

The display area can also be manipulated with the following controls in the Panel Options (or 'Viewer Canvas Manager') window. Use the wrench icon with a 'P' (or the 'Display Panel' menu) to show this window.

- Margins - specify the spacing for the left, right, top, and bottom margins
- Number of panels - specify the number of panels in x and y and the spacing between those panels.
- Background Color - white or black (more choices to come)
Figure 7.13: Selecting an image region with the polygon tool.
7.3.6.1 Setting up multi-panel displays

Figure 7.14 illustrates a multi-panel display along with the Viewer Canvas Manager settings which created it.

![Figure 7.14: A multi-panel display set up through the Viewer Canvas Manager.](image)

7.3.6.2 Background Color

The Background Color selection can be used to change the background color from its default of black. Currently, the only other choice is white, which is more appropriate for printing or inclusion in documents.

7.4 Viewing Measurement Sets

Visibility data can also be displayed and flagged directly from the viewer. For Measurement Set files the only option for display is 'Raster' (similar to AIPS task TVFLG). An example of MS display is shown in Figure 7.2; loading of an MS is shown in Figure 7.15.
Figure 7.15: The **Load Data - Viewer** panel as it appears if you select an MS. The only option available is to load this as a **Raster Image**. In this example, clicking on the **Raster Image** button would bring up the displays shown in Figure 7.2.

**Warning:** *Only one MS should be registered at a time on a Display Panel.* Only one MS can be shown in any case. You do not have to close other images/MSs, but you should at least ‘unregister’ them from the Display Panel used for viewing the MS. If you wish to see other images or MSs at the same time, create multiple Display Panel windows.

### 7.4.1 Data Display Options Panel for Measurement Sets

The **Data Display Options** panel provides adjustments for MSs similar to those for images, and also includes flagging options. As with images, this window appears when you choose the **Data:Adjust** menu or use the wrench icon from the **Main Toolbar**. It is also shown by default when an MS is loaded. The right panel of Figure 7.2 shows a **Data Options** window. It has a tab for each open MS, containing a set of categories. The options within each category can be either ‘rolled up’ or expanded by clicking the category label.

For a Measurement Set, the categories are:
• Advanced
• MS and Visibility Selection
• Display Axes
• Flagging Options
• Basic Settings
• Axis Drawing and Labels
• Color Wedge

7.4.1.1 MS Options — Basic Settings

The Basic Settings roll-up is expanded by default. It contains entries similar to those for a raster image (§7.3.1.1). Together with the brightness/contrast and colormap adjustment icons on the Mouse Toolbar of the Display Panel, they are especially important for adjusting the color display of your MS.

The available Basic options are:

• Data minimum/maximum
  This has the same usage as for raster images. Lowering the data maximum will help brighten weaker data values.

• Scaling power cycles
  This has exactly the same usage as for raster images (see §7.3.1.1). Again, lowering this value often helps make weaker data visible. If you want to view several fields with very different amplitudes simultaneously, this is typically one of the best adjustments to make early, together with the Colormap fiddling mouse tool, which is on the middle mouse button by default.

• Colormap
  Greyscale or Hot Metal colormaps are generally good choices for MS data.

7.4.1.2 MS Options — MS and Visibility Selections

• Visibility Type
• Visibility Component
• Moving Average Size
Figure 7.16: The MS for NGC4826 BIMA observations has been loaded into the viewer. We see the first of the spw in the Display Panel, and have opened up MS and Visibility Selections in the Data Display Options panel. The display panel raster is not full of visibilities because spw 0 is continuum and was only observed for the first few scans. This is a case where the different spectral windows have different numbers of channels also.

This roll-up provides choice boxes for Visibility Type (Observed, Corrected, Model, Residual) and Component (Amplitude, Phase, Real, or Imaginary).

Changes to Visibility Type or Component (changing from Phase to Amplitude, for example) require the data to be retrieved again from the disk into memory, which can be a lengthy process. When a large MS is first selected for viewing, the user must trigger this retrieval manually by pressing the Apply button (located below all the options), after selecting the data to be viewed (see Field IDs and Spectral Windows, below).

Tip: Changing visibility type between 'Observed' and 'Corrected' can also be used to assure that data and flags are reloaded from disk. You should do this if you’re using another flagging tool such as autoflag simultaneously, so that the viewer sees the other tool’s new edits and doesn’t overwrite them with obsolete flags. The Apply button alone won’t reload unless something within the viewer itself requires it; in the future, a button will be provided to reload flags from the disk unconditionally.

You can also choose to view the difference from a running mean or the local RMS deviation of either Phase or Amplitude. There is a slider for choosing the nominal number of time slots in the 'local neighborhood’ for these displays.
CHAPTER 7. VISUALIZATION WITH THE CASA VIEWER

(Note: **Insufficient Data** is shown in the tracking area during these displays when there is no other unflagged data in the local neighborhood to compare to the point in question. The moving time windows will not extend across changes in either field ID or scan number boundaries, so you may see this message if your scan numbers change with every time stamp. An option will be added later to ignore scan boundaries).

- **Field IDs**
- **Spectral Windows**

You can retrieve and edit a selected portion of the MS data by entering the desired Spectral Window and Field ID numbers into these boxes. **Important:** Especially with large MSs, often the first thing you’ll want to do is to select spectral windows which all have the **same number of channels** and the **same polarization setup**. It also makes sense to edit only a few fields at a time. Doing this will also greatly reduce data retrieval times and memory requirements.

You can separate the ID numbers with spaces or commas; you do not need to enter enclosing brackets. Changes to either entry box will cause the selected MS data to be reloaded from disk.

If you select, say, spectral windows 7, 8, 23, and 24, the animator, slice position sliders, and axis labeling will show these as 0, 1, 2, and 3 (the 'slice positions' or 'pixel coordinates' of the chosen spectral windows). Looking at the position tracking display is the best way to avoid confusion in such cases. It will show something like: **Sp Win 23 (s 2)** when you are viewing spectral window 23 (plane 2 of the selected spectral windows).

Changes to MS selections will not be allowed until you have saved (or discarded) any previous edits you have made (see **Flagging Options -- Save Edits**, below). A warning is printed on the console (not the logger).

Initially, all fields and spectral windows are selected. To revert to this 'unselected' state, choose 'Original' under the wrench icons next to the entry boxes.

See Figure [7.16](#) for an example showing the use of the **MS and Visibility Selections** controls when viewing an MS.

### 7.4.1.3 MS Options — Display Axes

This roll-up is very similar to that for images: it allows the user to choose which axes (from Time, Baseline, Polarization, Channel, and Spectral Window) are are on the display and the animator. There are also sliders here for choosing positions on the remaining axes. (It’s useful to note that the data *is* actually stored internally in memory as an array with these five axes).

For MSs, changing the choice of axis on one control will automatically swap axes, maintaining different axes on each control. Changing axes or slider/animator positions does not normally require pressing **Apply** — the new slice is shown immediately. However, the display may be partially or completely grey in areas if the required data is not currently in memory, either because no data has been loaded yet, or because not all the selected data will fit into the allowed memory.
Figure 7.17: The MS for NGC4826 from Figure 7.16 now with the Display Axes open in the Data Display Options panel. By default, channels are on the Animation Axis and thus in the tapedeck, while spectral window and polarization are on the Display Axes sliders.

Press the Apply button in this case to load the data (see §7.4.1.6 and Max. Visibility Memory at the end of §7.4.1.5).

Within the Display Axes rollup you may also select whether to order the baseline axis by antenna1-antenna2 (the default) or by (unprojected) baseline length.

See Figures 7.17, 7.18 showing the use of the Display Axes controls to change the axes on the animation and sliders.

7.4.1.4 MS Options — Flagging Options

These options allow you to edit (flag or unflag) MS data. The Crosshair and Rectangle Region Mouse Tools (§7.2.3) are used on the display to select the area to edit. When using the Rectangle Region tool, double-click inside the selected rectangle to confirm the edit.

The options below determine how edits will be applied.

- Show Flagged Regions...
Figure 7.18: The MS for NGC4826, continuing from Figure 7.17. We have now put spectral window on the Animation Axis and used the tapedeck to step to spw 2, where we see the data from the rest of the scans. Now channels is on a Display Axes slider, which has been dragged to show Channel 33.

You have the option to display flagged regions in the background color (as in TVFLG) or to highlight them with color. In the former case, flagged regions look just like regions of no data. With the (default) color option, flags are shown in shades of blue: darker blue for flags already saved to disk, lighter blue for new flags not yet saved; regions with no data will be shown in black.

- **Flag or Unflag**
  This setting determines whether selected regions will be flagged or unflagged. This does not affect previous edits; it only determines the effect which later edits will have. Both flagging and unflagging edits can be accumulated and then saved in one pass through the MS.

- **Flag/Unflag All...**
  These flagging extent checkboxes allow you to extend your edit over any of the five data axes. For example, to flag all the data in a given time range, you would check all the axes except Time, and then select the desired time range with the Rectangle Region mouse tool. Such edits will extend along the corresponding axes over the entire selected MS (whether loaded into memory or not) and optionally over unselected portions of the MS as well (Use Entire
MS, below). Use care in selecting edit extents to assure that you’re editing all the data you wish to edit.

- **Flag/Unflag Entire Antenna?**

  This control can be used to extend subsequent edits to all baselines which include the desired antenna[s]. For example, if you set this item to ‘Yes’ and then click the crosshair on a visibility point with baseline 3-19, the edit would extend over baselines 0-3, 1-3, 2-3, 3-3, 3-4, ... 3-\(n\)Antennas-1. Note that the second antenna of the selection (19) is irrelevant here – you can click anywhere within the ‘Antenna 3 block’, i.e., where the first antenna number is 3, to select all baselines which include antenna 3.

  This item controls the edit extent only along the baseline axis. If you wish to flag all the data for a given antenna, you must still check the boxes to flag all Times, Channels, Polarizations and Spectral Windows. There would be no point, however, in activating both this item and the ‘Flag All Baselines’ checkbox. You can flag an antenna in a limited range of times, etc., by using the appropriate checkboxes and selecting a rectangular region of visibilities with the mouse.

  **Note:** You do not need to include the entire ‘antenna block’ in your rectangle (and you may stray into the next antenna if you try). Anywhere within the block will work. To flag higher-numbered antennas, it often helps to zoom in.

- **Undo Last Edit**

- **Undo All Edits**

  The 'Undo' buttons do the expected thing: completely undo the effect of the last edit (or all unsaved edits). Please note, however, that only unsaved edits can be undone here; there is no ability to revert to the flagging state at the start of the session once flags have been saved to disk (unless you have previously saved a ‘flag version’. The flag version tool is not available through the viewer directly).

- **Use Entire MS When Saving Edits?**

  "Yes" means that saving the edits will flag/unflag over the entire MS, including fields (and possibly spectral windows) which are not currently selected for viewing. Specifically, data within time range(s) you swept out with the mouse (even for unselected fields) will be edited. In addition, if "Flag/Unflag All..." boxes were checked, such edits will extend throughout the MS. Note that only unselected times (fields) can be edited without checking extent boxes for the edits as well. Unselected spectral windows, e.g., will not be edited unless the edit also has "Flag/Unflag All Spectral Windows" checked.

  Warning: Beware of checking "All Spectral Windows" unless you have also checked "All Channels" or turned "Entire MS" off; channel edits appropriate to the selected spectral windows may not be appropriate to unselected ones. Set "Use Entire MS" to"No" if your edits need to apply only to the portion of the MS you have selected for viewing. Edits can often be saved significantly faster this way as well.

  Also note that checkboxes apply to individual edits, and must be checked before making the edit with the mouse. "Use Entire MS", on the other hand, applies to all the edits saved at one time, and must be set as desired before pressing "Save Edits".
• Save Edits

MS editing works like a text editor in that you see all of your edits immediately, but nothing is committed to disk until you press 'Save Edits'. Feel free to experiment with all the other controls; nothing but 'Save Edits' will alter your MS on disk. As mentioned previously, however, there is no way to undo your edits once they are saved, except by manually entering the reverse edits (or restoring a previously-saved 'flag version').

Also, you must save (or discard) your edits before changing the MS selections. If edits are pending, the selection change will not be allowed, and a warning will appear on the console.

If you close the MS in the viewer, unsaved edits are simply discarded, without prior warning. It’s important, therefore, to remember to save them yourself. You can distinguish unsaved flags (when using the 'Flags In Color’ option), because they are in a lighter shade of blue.

The program must make a pass through the MS on disk to save the edits. This can take a little time; progress is shown in the console window.

7.4.1.5 MS Options— Advanced

These settings can help optimize your memory usage, especially for large MSs. A rule of thumb is that they can be increased until response becomes sluggish, when they should be backed down again.

You can run the unix 'top' program and hit 'M' in it (to sort by memory usage) in order to examine the effects of these settings. Look at the amount of RSS (main memory) and SWAP used by the X server and 'casaviewer' processes. If that sounds familiar and easy, then fiddling with these settings is for you. Otherwise, the default settings should provide reasonable performance in most cases.

• Cache size

The value of this option specifies the maximum number of different views of the data to save so that they can be redrawn quickly. If you run an animation or scroll around zoomed data, you will notice that the data displays noticeably faster the second time through because of this feature. Often, setting this value to the number of animation frames is ideal. Note, however, that on multi-panel displays, each panel counts as one cached image.

Large images naturally take more room than small ones. The memory used for these images will show up in the X server process. If you need more Visibility Memory (below) for a really large ms, it is usually better to forgo caching a large number of views.

• Max. Visibility Memory

This option specifies how many megabytes of memory may be used to store visibility data from the measurement set internally. Even if you do not adjust this entry, it is useful to look at it to see how many megabytes are required to store your entire (selected) MS in memory. If the slider setting is above this, the whole selected MS will fit into the memory buffer. Otherwise, some data planes will be ‘greyed out’ (see Apply Button, § 7.4.1.6 below), and the selected data will have to be viewed one buffer at a time, which is somewhat less convenient. In most cases, this means you should select fewer fields or spectral windows – see § 7.4.1.2.
CHAPTER 7. VISUALIZATION WITH THE CASA VIEWER

The 'casaviewer' process contains this buffer memory (it contains the entire viewer, but the memory buffer can take most of the space).

7.4.1.6 MS Options — Apply Button

When viewing large MSs the display may be partially or completely grey in areas where the required data is not currently in memory, either because no data has been loaded yet, or because not all the selected data will fit into the allowed memory (see Max. Visibility Memory above). When the cursor is over such an area, the following message shows in the position tracking area:

press 'Apply' on Adjust panel to load data

Pressing the Apply button (which lies below all the options) will reload the memory buffer so that it includes the slice you are trying to view.

The message No Data has a different meaning; in that case, there simply is no data in the selected MS at the indicated position.

For large measurement sets, loading visibility data into memory is the most time-consuming step. Progress feedback is provided in the console window. Again, careful selection of the data to be viewed can greatly speed up retrieval.

7.5 Printing from the Viewer

You can use the Data:Print menu or the Print button to bring up the Viewer Print Manager. From this panel, you can print a hardcopy of what is in the Display Panel, or save it in a variety of formats.

Figure 7.19 shows an example of printing to a file. The key to making acceptable hardcopies (particularly for printing or inclusion in documents) is to set the background color and line widths to appropriate values so the plot and labels show up in the limited resolution of the hardcopy.

Use the Viewer Canvas Manager (§7.3.6) to change the Background Color from its default of black to white if you are making plots for printing or inclusion in a document. You might also want to change the colormap accordingly.

Adjust the Line Width of the Axis Label Properties options in the Data Display Options panel so that the labels will be visible when printed. Increasing from the default of 1.4 to a value around 2 seems to work well.

You can choose an output file name in the panel. Be sure to make it a new name, otherwise it will not overwrite a previous file (and will not say anything about it).

If you will be printing to a postscript printer or to a PS or EPS file, dial up the [PS] Resolution (dpi) to its maximum of 600. This will increase the size of the PS file somewhat, but will make a much better plot. Use gzip to compress the PS file if necessary. Be sure to choose the desired Output Media and Orientation for PS also.
Figure 7.19: Setting up to print to a file. The background color has been set to white, the line width to 2, and the print resolution to 600 dpi (for a postscript plot). To make the plot, use the Save button on the Viewer Print Manager panel (positioned in the figure in the upper right) and select a format with the drop-down, or use the Print button to send directly to a printer.

**BETA ALERT:** The postscript printing capabilities of the casaviewer are currently limited due to some issues with the way we use Qt and do axis labels. Significant improvements have been made in Patch 3. This will be further upgraded in the future, but for now you will need to follow the suggestions above to get a usable plot. Note that ghostview may show a poorer version of the PS than you will get when you print.
Appendix A

Single Dish Data Processing

**BETA ALERT:** The single-dish analysis package within CASA is still experimental. It is included in the Beta release for the use of the ALMA computing and commissioning groups, and is not intended for general users. Therefore, this is included in this Cookbook as an appendix.

For single-dish spectral calibration and analysis, CASA uses the ATNF Spectral Analysis Package (ASAP). This is imported as the \texttt{sd} tool, and forms the basis for a series of tasks (the \textquotedblleft SDtasks\textquotedblright) that encapsulate the functionality within the standard CASA task framework. ASAP was developed to support the Australian telescopes such as Mopra, Parkes, and Tidbinbilla, and we have adapted it for use within CASA for GBT and eventually ALMA data also [Note: some support for the ALMA data are now available]]. For Patch 4, **ASAP included in CASA was updated to Version 2.2.** For details on ASAP, see the ASAP home page at ATNF:

- \url{http://www.atnf.csiro.au/computing/software/asap/}

You can also download the ASAP User Guide and Reference Manual at this web site. There is also a brief tutorial. Note that within CASA, the ASAP tools are prefaced with \texttt{sd.}, e.g. where it says in the ASAP User Guide to use \texttt{scantable} you will use \texttt{sd.scantable} in CASA. See §A.3 for more information on the tools.

All of the ASAP functionality is available with a CASA installation. In the following, we outline how to access ASAP functionality within CASA with the tasks and tools, and the data flow for standard use cases.

If you run into trouble, be sure to check the list of known issues and features of ASAP and the SDtasks presented in §A.5 first.

A.1 Guidelines for Use of ASAP and SDtasks in CASA

A.1.1 Environment Variables

There are a number of environment variables that the ASAP tools (and thus the SDtasks) use to help control their operation. These are described in the ASAP User Guide as being in the \texttt{.asaprc}
file. Within CASA, these are contained in the Python dictionary \texttt{sd.rcParams} and are accessible through its keys and values. For SDtask users, the most important are the \texttt{verbose} parameter controlling the display of detailed messages from the tools. By default

\begin{verbatim}
    sd.rcParams['verbose'] = True
\end{verbatim}

and you get lots of messages. Also, the \texttt{scantable.storage} parameter controlling whether scantable operations are done in memory or on disk. The default

\begin{verbatim}
    sd.rcParams['scantable.storage'] = 'memory'
\end{verbatim}

does it in memory (best choice if you have enough), while to force the scantables to disk use

\begin{verbatim}
    sd.rcParams['scantable.storage'] = 'disk'
\end{verbatim}

which might be necessary to allow processing of large datasets. See §\ref{subsec:environment-variables} for more details on the ASAP environment variables.

\subsection{Assignment}

Some ASAP methods and function require you to assign that method to a variable which you can then manipulate. This includes \texttt{sd.scantable} and \texttt{sd.selector}, which make objects. For example,

\begin{verbatim}
    s = sd.scantable('OrionS_rawACSmod', average=False)
\end{verbatim}

\subsection{Lists}

For lists of scans or IFs, such as in \texttt{scanlist} and \texttt{iflist} in the SDtasks, the tasks and functions want a comma-separated Python list, e.g.

\begin{verbatim}
    scanlist = [241, 242, 243, 244, 245, 246]
\end{verbatim}

You can use the Python \texttt{range} function to generate a list of consecutive numbers, e.g.

\begin{verbatim}
    scanlist = range(241,247)
\end{verbatim}

giving the same list as above, e.g.

\begin{verbatim}
CASA <3>: scanlist=range(241,247)
CASA <4>: print scanlist
[241, 242, 243, 244, 245, 246]
\end{verbatim}

You can also combine multiple ranges by summing lists
CASA <5>: scanlist=range(241,247) + range(251,255)
CASA <6>: print scanlist
[241, 242, 243, 244, 245, 246, 251, 252, 253, 254]

Note that in the future, the sd tools and SDtasks will use the same selection language as in the synthesis part of the package.

Spectral regions, such as those for setting masks, are pairs of min and max values for whatever spectral axis unit is currently chosen. These are fed into the tasks and tools as a list of lists, with each list element a list with the [min,max] for that sub-region, e.g.

\[
\text{masklist} = [[1000,3000], [5000,7000]].
\]

### A.1.4 Dictionaries

Currently, the SDtasks return the Python dictionary for the results of line fitting (in sdfit) and region statistics (in sdstat). If you invoke these tasks by assigning variable for the return, you can then access the elements of these through the keywords, e.g.

CASA <10>: line_stat=sdstat()  
Current fluxunit = K  
No need to convert fluxunits  
Using current frequency frame  
Using current doppler convention

CASA <11>: line_stat
  Out[11]:  
  {'equw': 70.861755476162784,  
  'max': 1.2750182151794434,  
  'mean': 0.35996028780937195,  
  'median': 0.23074722290039062,  
  'min': -0.20840644836425781,  
  'rms': 0.53090775012969971,  
  'stddev': 0.39102539420127869,  
  'sum': 90.350028991699219}

You can then use these values in scripts by accessing this dictionary, e.g.

CASA <12>: print "Line max = \%5.3f K" % (line_stat['max'])  
Line max = 1.275 K

for example.

### A.1.5 Line Formatting

The SDtasks trap leading and trailing whitespace on string parameters (such as infile and sdfile), but ASAP does not, so be careful with setting string parameters. ASAP is also case-sensitive, with most parameters being upper-case, such as ASAP for the sd.scantable.save file format. The SDtasks are generally more forgiving.
Also, beware Python’s sensitivity to indenting.

A.2 Single Dish Analysis Tasks

A set of single dish tasks is available for simplifying basic reduction activities. Currently the list includes:

- **sdaverage** — select, calibrate, and average SD data
- **sdsMOOTH** — smooth SD spectra
- **sdbaseline** — fit/remove spectral baselines from SD data
- **sdcal** — combined the three tasks above to perform standard single dish processing all at once
- **sdcoadd** — merge/co-add multiple SD data
- **sdfit** — line fitting to SD spectra
- **sdlist** — print a summary of a SD dataset
- **sdmath** — do simple arithmetic for SD spectra
- **sdplot** — plotting of SD spectra, including overlay of line catalog data
- **sdsave** — save SD data to different format
- **sdscale** — scale SD data
- **sdstat** — compute statistics of regions of SD spectra
- **sdtpimaging** — do a simple calibration and create an image from the total power raster scans

All of the SD tasks work from a file on disk rather than from a scantable in memory as the ASAP toolkit does (see §A.3). Inside the tasks we invoke a call to *sd.scantable* to read in the data. The scantable objects do not persist within CASA after completion of the tasks, and are destroyed to free up memory.

Three tasks **sdaverage**, **sdsMOOTH**, and **sdbaseline** are the workhorse for the calibration, selection, averaging, baseline fitting, and smoothing. The output datasets for each task are written to a file on disk. Alternatively, one can use the task **sdcal** to perform all the steps in the three tasks described above in a single task invocation. It is comparable to run **sdaverage**, **sdsMOOTH**, and **sdbaseline**, in that order, since **sdcal** internally calls these three tasks. Its operation is controlled by three main "mode" parameters: **calmode** (which selects the type of calibration, if any, to be applied),

...
Appendix A. Appendix: Single Dish Data Processing

Kernel (which selects the smoothing), and blmode (which selects baseline fitting). There are also parameters controlling the selection such as scanlist, iflist, field, scanaverage, timeaverage, and polaverage. Note that sdcal can be run with calmode='none' to allow re-selection or writing out of data that is already calibrated.

There is a "wiring diagram" of the dataflow and control inputs for sdcal shown in Figure A.1. This might help you chart your course through the calibration.

The SDtasks support the import and export file formats supported by ASAP itself. For import, this includes: ASAP (scantables), MS (CASA measurement set), RPFITS and SDFITS. For export, this includes: ASAP (scantables), MS (CASA measurement set), ASCII (text file), SDFITS (a flavor of SD FITS). The sdsave task is available exclusively for exporting with data selection options.

The sdcoadd task is available to merge data in separate data files into one.

You can get a brief summary of the data in a file using the sdlist task.

Plotting of spectra is handled in the sdplot task. It also offers some selection, averaging and smoothing options in case you are working from a dataset that has not been split or averaged. Note that there is some rudimentary plotting capability in many of SD tasks, controlled through the plotlevel parameter, to aid in the assessment of the performance of these tasks.

Scaling of the spectra and Tsys is available in the sdscale. For arithmetic operations of spectra in separate scantables, a new task, sdmath is added.

Calculation of statistics on spectral regions is available in the sdstat task. Results are passed in a Python dictionary return variable.

Basic Gaussian line-fitting is handled by the sdfit task. It can deal with the simpler cases, and offers some automation as well as interactive selection of fitting region, but more complicated fitting is best accomplished through the toolkit (sd.fitter).

Basic non-interactive channel flagging is available in the sdflag task. By default or by specifying outfile parameter, a new file is created containing dataset with the flag information. To update flags in the input data, outfile='none' must be set.

Limited total power data analysis functionality is available through the task, sdtpimaging. This task directly access the Measurement Set without converting it to scantable format.
Figure A.1: Wiring diagram for the SDtask `sdcal`. The stages of processing within the task are shown, along with the parameters that control them.
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

A.2.1 SDtask Summaries

The following are the list of parameters and brief descriptions of each of the SDtasks. These descriptions are also contained in the information produced by help <taskname>, once asap.init has been invoked. Note that you can use inp <taskname> on these as for other tasks.

A.2.1.1 sdaverage

Keyword arguments:

sdfile -- name of input SD dataset
fluxunit -- units for line flux
    options: 'K','Jy',''
    default: '' (keep current fluxunit)
    WARNING: For GBT data, see description below.
>>> fluxunit expandable parameter
telescopeparm -- the telescope characteristics
    options: (str) name or (list) list of gain info
    default: '' (none set)
    example: if telescopeparm='', it tries to get the telescope name from the data.
    Full antenna parameters (diameter,ap.eff.) known to ASAP are 'ATPKSMB', 'ATPKSHOH', 'ATMOPRA', 'DSS-43', 'CEDUNA','HOBART'. For GBT, it fixes default fluxunit to 'K' first then convert to a new fluxunit.
telescopeparm=[104.9,0.43] diameter(m), ap.eff.
telescopeparm=[0.743] gain in Jy/K
telescopeparm='FIX' to change default fluxunit
    see description below

specunit -- units for spectral axis
    options: (str) 'channel','km/s','GHz','MHz','kHz','Hz'
    default: '' (=current)
    example: this will be the units for masklist

frame -- frequency frame for spectral axis
    options: (str) 'LSRK','REST','TOPO','LSRD','BARY', 'GEO','GALACTO','LGROUP','CMB'
    default: currently set frame in scantable
    WARNING: frame='REST' not yet implemented

doppler -- doppler mode
    options: (str) 'RADIO','OPTICAL','Z','BETA','GAMMA'
    default: currently set doppler in scantable

calmode -- calibration mode
    options: 'ps','nod','fs','fsotf','quotient','none'
default: 'none'
example: choose mode 'none' if you have
    already calibrated and want to
    try averaging

scanlist -- list of scan numbers to process
default: [] (use all scans)
example: [21,22,23,24]
    this selection is in addition to field,
    iflist, and pollist

field -- selection string for selecting scans by name
default: '' (no name selection)
example: 'FLS3a*'
    this selection is in addition to scanlist,
    iflist, and pollist

iflist -- list of IF id numbers to select
default: [] (use all IFs)
example: [15]
    this selection is in addition to scanlist,
    field, and pollist

pollist -- list of polarization id numbers to select
default: [] (use all polarizations)
example: [1]
    this selection is in addition to scanlist,
    field, and iflist

channelrange -- channel range selection
default: [] (use all channel)
example: [0,5000]
    Note that specified values are recognized as
    'channel' regardless of the value of specunit

scanaverage -- average integrations within scans
options: (bool) True,False
default: False
example: if True, this happens in read-in
    For GBT, set False!

timeaverage -- average times for multiple scan cycles
options: (bool) True,False
default: False
example: if True, this happens after calibration

>>>timeaverage expandable parameter
tweight -- weighting for time average
options: 'none'
    'var'  (1/var(spec) weighted)
    'tsys'  (1/Tsys**2 weighted)
    'tint'  (integration time weighted)
    'tintsys'  (Tint/Tsys**2)
'median' (median averaging)
default: 'none'

averageall -- average multi-resolution spectra
spectra are averaged by referring
their frequency coverage
default: False

polaverage -- average polarizations
options: (bool) True, False
default: False

>>>polaverage expandable parameter
pweight -- weighting for polarization average
options: 'none'
    'var' (1/var(spec) weighted)
    'tsys' (1/Tsys**2 weighted)
default: 'none'

tau -- atmospheric optical depth
default: 0.0 (no correction)

outfile -- Name of output file
default: ' ( <sdfile>_cal)

outform -- format of output file
options: 'ASCII', 'SDFITS', 'MS', 'ASAP'
default: 'ASAP'
example: the ASAP format is easiest for further sd
processing; use MS for CASA imaging.
If ASCII, then will append some stuff to
the outfile name

overwrite -- overwrite the output file if already exists
options: (bool) True, False
default: False
WARNING: if outform='ASCII', this parameter is ignored

plotlevel -- control for plotting of results
options: (int) 0=none, 1=some, 2=more, <0=hardcopy
default: 0 (no plotting)
example: plotlevel<0 as abs(plotlevel), e.g.
-1 => hardcopy of final plot (will be named
<outfile>_calspec.eps)

WARNING: be careful plotting in fsotf mode!

DESCRIPTION:
Task sdaverage performs data selection, calibration for single-dish spectra. By setting calmode='none'
one can run sdaverage on already calibrated data, for further selection, averaging and atmospheric
optical depth correction.
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

If you give multiple IFs in iflist, then your scantable will have multiple IFs. This can be handled, but there can be funny interactions later on. We recommend you split each IF out into separate files by re-running sdaverage with each IF in turn unless you want to averaging of multi-resolution spectra (see below).

To save the output spectra in a certain range of channels, you set the range in channelrange. Averaging of multi-resolution spectra can be achieved by setting the sub-parameter in timeaverage, averageall to True. It generally handles multi-IFs by selecting overlaps in IFs and assigning new IFs in the output spectra.

ASAP recognizes the data of the "AT" telescopes, but currently does not know about the GBT or any other telescope. This task does know about GBT. Telescope name is obtained from the data. If you wish to change the fluxunit (see below), by leaving the sub-parameter telescopeparm unset (telescopeparm=''), it will use internal telescope parameters for flux conversion for the data from AT telescopes and it will use an approximate aperture efficiency conversion for the GBT data. If you give telescopeparm a list, then if the list has a single float it is assumed to be the gain in Jy/K, if two or more elements they are assumed to be telescope diameter (m) and aperture efficiency respectively.

Note that sdaverage assumes that the fluxunit is set correctly in the data already. If not, then set telescopeparm='FIX' and it will set the default units to fluxunit without conversion. NOTE: If the data in sdfile is an ms from GBT and the default flux unit is missing, this task automatically fixes the default fluxunit to 'K' before the conversion.

A.2.1.2 sdsmooth

Keyword arguments:

sdfile -- name of input SD dataset
scanaverage -- average integrations within scans
    options: (bool) True, False
    default: False
    example: if True, this happens in read-in
    For GBT, set False!
scanlist -- list of scan numbers to process
    default: [] (use all scans)
    example: [21,22,23,24]
    this selection is in addition to field, iflist, and pollist
field -- selection string for selecting scans by name
    default: '' (no name selection)
    example: 'FLS3a*'  
    this selection is in addition to scanlist, iflist,pollist
iflist -- list of IF id numbers to select
    default: [] (use all IFs)
    example: [15]
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

this selection is in addition to scanlist, field, and pollist

pollist -- list of polarization id numbers to select
default: [] (use all polarizations)
exmple: [1]
this selection is in addition to scanlist, field, and iflist

kernel -- type of spectral smoothing
options: 'hanning','gaussian','boxcar'
default: 'hanning'

>>>kernel expandable parameter
kwidth -- width of spectral smoothing kernel
options: (int) in channels
default: 5
example: 5 or 10 seem to be popular for boxcar
(0 will turn off gaussian or boxcar)

outfile -- Name of output ASAP format(scantable) file
default: '' (<sdfile>_sm)

outform -- format of output file
options: 'ASCII','SDFITS','MS','ASAP'
default: 'ASAP'
example: the ASAP format is easiest for further sd
processing; use MS for CASA imaging.

overwrite -- overwrite the output file if already exists
options: (bool) True,False
default: False
WARNING: if outform='ASCII', this parameter is ignored

plotlevel -- control for plotting of results
options: (int) 0=none, 1=some, 2=more, <0=hardcopy
default: 0 (no plotting)
example: plotlevel<0 as abs(plotlevel), e.g.
-1 => hardcopy of final plot (will be named
<outfile>_smspec.eps)

DESCRIPTION:
Task sdsmooth performs smoothing of the single-dish spectra. Set plotlevel <= 1 to plot spectrum before and after smoothing.

A.2.1.3 sdbaseline

Keyword arguments:
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

sdfile -- name of input SD dataset
fluxunit -- units for line flux
   options: 'K','Jy',''
   default: '' (keep current fluxunit)
   WARNING: For GBT data, see description below.
   >>> fluxunit expandable parameter
   telescopeparm -- the telescope characteristics
      options: (str) name or (list) list of gain info
      default: '' (none set)
      example: if telescopeparm='', it tries to get the telescope name from the data.
      Full antenna parameters (diameter,ap.eff.) known to ASAP are
      'ATPKSMB', 'ATPKSHOH', 'ATMOPRA', 'DSS-43',
      'CEDUNA', 'HOBART'. For GBT, it fixes default fluxunit to 'K' first then convert to a new fluxunit.
      telescopeparm=[104.9,0.43] diameter(m), ap.eff.
      telescopeparm=[0.743] gain in Jy/K
      telescopeparm='FIX' to change default fluxunit
      see description below
specunit -- units for spectral axis
   options: (str) 'channel','km/s','GHz','MHz','kHz','Hz'
   default: '' (=current)
   example: this will be the units for masklist
frame -- frequency frame for spectral axis
   options: (str) 'LSRK','REST','TOPO','LSRD','BARY','
   'GEO','GALACTO','LGROUP','CMB'
   default: currently set frame in scantable
   WARNING: frame='REST' not yet implemented
doppler -- doppler mode
   options: (str) 'RADIO','OPTICAL','Z','BETA','GAMMA'
   default: currently set doppler in scantable
scanlist -- list of scan numbers to process
   default: [] (use all scans)
   example: [21,22,23,24]
   this selection is in addition to field, iflist, and pollist
field -- selection string for selecting scans by name
   default: '' (no name selection)
   example: 'FLS3a*
       this selection is in addition to scanlist, iflist, and pollist
iflist -- list of IF id numbers to select
   default: [] (use all IFs)
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

example: [15]
  this selection is in addition to scanlist,
  field, and pollist

pollist -- list of polarization id numbers to select
default: [] (use all polarizations)
example: [1]
  this selection is in addition to scanlist,
  field, and iflist

tau -- atmospheric optical depth
default: 0.0 (no correction)

blmode -- mode for baseline fitting
options: (str) 'auto','list','interact'
default: 'auto'
example: blmode='auto' uses expandable parameters
  in addition to blpoly to run linefinder
  to determine line-free regions
  USE WITH CARE! May need to tweak the parameters,
  thresh, avg_limit, and edge.
  blmode='interact' allows adding and deleting mask
  regions by drawing rectangles on the plot with mouse.
  Draw a rectangle with LEFT-mouse to ADD the region to
  the mask and with RIGHT-mouse to DELETE the region.

>>> blmode expandable parameters

thresh -- S/N threshold for linefinder
default: 5
example: a single channel S/N ratio above which the channel is
  considered to be a detection

avg_limit -- channel averaging for broad lines
default: 4
example: a number of consecutive channels not greater than
  this parameter can be averaged to search for broad lines

edge -- channels to drop at beginning and end of spectrum
default: 0
example: [1000] drops 1000 channels at beginning AND end
  [1000,500] drops 1000 from beginning and 500 from end

Note: For bad baselines threshold should be increased,
  and avg_limit decreased (or even switched off completely by
  setting this parameter to 1) to avoid detecting baseline
  undulations instead of real lines.

blpoly -- order of baseline polynomial
options: (int) (<0 turns off baseline fitting)
default: 5
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

example: typically in range 2-9 (higher values seem to be needed for GBT)

**verify** -- verify the results of baseline fitting
options: (bool) True,False
default: False
WARNING: Currently this just asks whether you accept the displayed fit and if not, continues without doing any baseline fit.

**masklist** -- list of mask regions to INCLUDE in BASELINE fit
default: [] (entire spectrum)
example: [[1000,3000],[5000,7000]]
if blmode='auto' then this mask will be applied before fitting

**outfile** -- Name of output file
default: '' (<sdfile>_bs)

**outform** -- format of output file
options: 'ASCII','SDFITS','MS','ASAP'
default: 'ASAP'
example: the ASAP format is easiest for further sd processing; use MS for CASA imaging. If ASCII, then will append some stuff to the outfile name

**overwrite** -- overwrite the output file if already exists
options: (bool) True,False
default: False
WARNING: if outform='ASCII', this parameter is ignored

**plotlevel** -- control for plotting of results
options: (int) 0=none, 1=some, 2=more, <0=hardcopy
default: 0 (no plotting)
example: plotlevel<0 as abs(plotlevel), e.g.
-1 => hardcopy of final plot (will be named <outfile>_bspec.eps)
WARNING: be careful plotting in fsotf mode!

**DESCRIPTION:**

Task **sdbaseline** performs baseline fitting/removal for single-dish spectra. The fit parameters, terms and rms of base-line are saved to an ASCII file, `<outfile>_blparam.txt`

Also, see the notes on **fluxunit** and **telescopeparm** in the section for **sdaverage**. See the **sdaverage** description for information on **fluxunit** conversion and the **telescopeparm** parameter.

By setting **blmode='interact'**, you can set/unset mask regions interactively using mouse buttons. Current mask regions will be shown in yellow shade in the plot. Baseline fit parameters and rms of fitted spectra are automatically saved to an ASCII file, `<outfile>_blparam.txt`.
Beta Patch 4 New Features: The parameter, interactive, is renamed to verify.

A.2.1.4 sdcal

Keyword arguments:

- **sdfile** -- name of input SD dataset
- **fluxunit** -- units for line flux
  - options: 'K', 'Jy', ''
  - default: '' (keep current fluxunit)
  - WARNING: For GBT data, see description below.
  - >>> fluxunit expandable parameter
- **telescopeparm** -- the telescope characteristics
  - options: (str) name or (list) list of gain info
  - default: '' (none set)
  - example: if telescopeparm='', it tries to get the telescope name from the data.
  - Full antenna parameters (diameter,ap.eff.) known to ASAP are
    'ATPKSMB', 'ATPKSHOH', 'ATMOPRA', 'DSS-43', 'CEDUNA', 'HOBART'. For GBT, it fixes default fluxunit to 'K' first then convert to a new fluxunit.
  - telescopeparm=[104.9,0.43] diameter(m), ap.eff.
  - telescopeparm=[0.743] gain in Jy/K
  - telescopeparm='FIX' to change default fluxunit
  - see description below

- **specunit** -- units for spectral axis
  - options: (str) 'channel', 'km/s', 'GHz', 'MHz', 'kHz', 'Hz', ''
  - default: '' (=current)
  - example: this will be the units for masklist

- **frame** -- frequency frame for spectral axis
  - options: (str) 'LSRK', 'REST', 'TOPO', 'LSRD', 'BARY', 'GEO', 'GALACTO', 'LGROUP', 'CMB'
  - default: currently set frame in scantable
  - WARNING: frame='REST' not yet implemented

- **doppler** -- doppler mode
  - options: (str) 'RADIO', 'OPTICAL', 'Z', 'BETA', 'GAMMA'
  - default: currently set doppler in scantable

- **calmode** -- calibration mode
  - options: 'ps', 'nod', 'fs', 'fsotf', 'quotient', 'none'
  - default: 'none'
  - example: choose mode 'none' if you have already calibrated and want to try baselines or averaging
scanlist -- list of scan numbers to process
  default: [] (use all scans)
  example: [21, 22, 23, 24]
  this selection is in addition to field, iflist, and pollist

field -- selection string for selecting scans by name
  default: '' (no name selection)
  example: 'FLS3a*
  this selection is in addition to scanlist, iflist, and pollist

iflist -- list of IF id numbers to select
  default: [] (use all IFs)
  example: [15]
  this selection is in addition to scanlist, field, and pollist

pollist -- list of polarization id numbers to select
  default: [] (use all polarizations)
  example: [1]
  this selection is in addition to scanlist, field, and iflist

channelrange -- channel range selection
  default: [] (use all channel)
  example: [0, 5000]
  Note that specified values are recognized as 'channel' regardless of the value of specunit

average -- averaging on spectral data
  options: (bool) True, False
  default: False

>>>average expandable parameter

scanaverage -- average integrations within scans
  options: (bool) True, False
  default: False
  example: if True, this happens in read-in
  For GBT, set False!

timeaverage -- average times for multiple scan cycles
  options: (bool) True, False
  default: False
  example: if True, this happens after calibration

tweight -- weighting for time average
  options: 'none'
  'var'  (1/var(spec) weighted)
  'tsys' (1/Tsys**2 weighted)
  'tint' (integration time weighted)
  'tintsys' (Tint/Tsys**2)
  'median' (median averaging)
default: 'none'

averageall -- average multi-resolution spectra
spectra are averaged by referring
to their frequency coverage
default: False

polaverage -- average polarizations
options: (bool) True, False
default: False

pweight -- weighting for polarization average
options: 'none'
          'var' (1/var(spec) weighted)
          'tsys' (1/Tsys**2 weighted)

tau -- atmospheric optical depth
default: 0.0 (no correction)

kernel -- type of spectral smoothing
options: 'none', 'hanning', 'gaussian', 'boxcar'
default: 'none'

>>> kernel expandable parameter

kwidth -- width of spectral smoothing kernel
options: (int) in channels
default: 5
example: 5 or 10 seem to be popular for boxcar
         ignored for hanning (fixed at 5 channels)
         (0 will turn off gaussian or boxcar)

blmode -- mode for baseline fitting
options: (str) 'none', 'auto', 'list', 'interact'
default: 'none'
example: blmode='auto' uses expandable parameters
         in addition to blpoly to run linefinder
         to determine line-free regions
         USE WITH CARE! May need to tweak the parameters,
thresh, avg_limit, and edge.
         blmode='interact' allows adding and deleting mask
         regions by drawing rectangles on the plot with mouse.
         Draw a rectangle with LEFT-mouse to ADD the region to
         the mask and with RIGHT-mouse to DELETE the region.

>>> blmode expandable parameters

thresh -- S/N threshold for linefinder
default: 5
example: a single channel S/N ratio above which the channel is
considered to be a detection

avg_limit -- channel averaging for broad lines
default: 4
example: a number of consecutive channels not greater than
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

this parameter can be averaged to search for broad lines

edge -- channels to drop at beginning and end of spectrum
default: 0
example: [1000] drops 1000 channels at beginning AND end
[1000,500] drops 1000 from beginning and 500 from end

Note: For bad baselines threshold should be increased,
and avg_limit decreased (or even switched off completely by
setting this parameter to 1) to avoid detecting baseline
undulations instead of real lines.

blpoly -- order of baseline polynomial
options: (int) (<0 turns off baseline fitting)
default: 5
typical in range 2-9 (higher values
seem to be needed for GBT)

verify -- verify the results of baseline fitting
options: (bool) True,False
default: False
WARNING: Currently this just asks whether you accept
the displayed fit and if not, continues
without doing any baseline fit.

masklist -- list of mask regions to INCLUDE in BASELINE fit
default: [] (entire spectrum)
example: [[1000,3000],[5000,7000]]
if blmode='auto' then this mask will be applied
before fitting

outfile -- Name of output file
default: '' (<sdfile>_cal)

outform -- format of output file
options: 'ASCII','SDFITS','MS','ASAP'
default: 'ASAP'
example: the ASAP format is easiest for further sd
processing; use MS for CASA imaging.
If ASCII, then will append some stuff to
the outfile name

overwrite -- overwrite the output file if already exists
options: (bool) True,False
default: False
WARNING: if outform='ASCII', this parameter is ignored

plotlevel -- control for plotting of results
options: (int) 0=none, 1=some, 2=more, <0=hardcopy
default: 0 (no plotting)
exmple: plotlevel<0 as abs(plotlevel), e.g.
-1 => hardcopy of final plot (will be named
DESCRIPTION:

Task `sdcal` performs data selection, calibration, and/or spectral baseline fitting for single-dish spectra. This task internally calls the tasks, `sdaverage`, `sdsmooth`, and `sdbaseline` and it can be used to run all the three steps in one task execution. By setting `calmode='none'` one can run `sdcal` on already calibrated data, for further selection, averaging and atmospheric optical depth correction. See the `sdaverage` description for information on `fluxunit` conversion and the `telescopeparm` parameter. To save the output spectra in a certain range of channels, you set the range in `channelrange`. Averaging of multi-resolution spectra can be achieved by setting the sub-parameter of `average`, `averageall` to True. It generally handles multi-IFs by selecting overlaps in IFs and assigning new IFs in the output spectra.

**Beta Patch 4 New Features:**

1. Interactive mask selection for baseline fitting is enabled with `blmode='interact'`

2. The parameter `interactive` is renamed as `verify`

**A.2.1.5 sdcoadd**

Keyword arguments:

- `sdfilelist` -- list of names of input SD dataset
- `fluxunit` -- units for line flux
  - options: 'K', 'Jy', ''
  - default: '' (keep current fluxunit)
  - WARNING: For GBT data, see description below.

```python
>>> fluxunit expandable parameter
```

- `telescopeparm` -- the telescope characteristics
  - options: (str) name or (list) list of gain info
  - default: '' (none set)
  - example: if `telescopeparm='',` it tries to get the telescope name from the data.
  - Full antenna parameters (diameter,ap.eff.) known to ASAP are
    - 'ATPKSMB', 'ATPKSHOH', 'ATMOPRA', 'DSS-43',
    - 'CEDUNA', 'HOBART'. For GBT, it fixes default fluxunit to 'K' first then convert to a new fluxunit.
  - `telescopeparm=[104.9,0.43]` diameter(m), ap.eff.
  - `telescopeparm=[0.743]` gain in Jy/K
  - `telescopeparm='FIX'` to change default fluxunit

see description below
specunit -- units for spectral axis
  options: (str) 'channel', 'km/s', 'GHz', 'MHz', 'kHz', 'Hz'
  default: '' (=current)
  example: this will be the units for masklist
frame -- frequency frame for spectral axis
  options: (str) 'LSRK', 'REST', 'TOPO', 'LSRD', 'BARY',
           'GEO', 'GALACTO', 'LGROUP', 'CMB'
  default: currently set frame in scantable
  WARNING: frame='REST' not yet implemented
doppler -- doppler mode
  options: (str) 'RADIO', 'OPTICAL', 'Z', 'BETA', 'GAMMA'
  default: currently set doppler in scantable
scanaverage -- average integrations within scans
  options: (bool) True, False
  default: False
  example: if True, this happens in read-in
           For GBT, set False!
timeaverage -- average times for multiple scan cycles
  options: (bool) True, False
  default: False
  example: if True, this happens after calibration
polaverage -- average polarizations
  options: (bool) True, False
  default: False
outfile -- Name of output file
  default: '' (scantable)
  example:
outform -- format of output file
  options: 'ASCII', 'SDFITS', 'MS', 'ASAP'
  default: 'ASAP'
  example: the ASAP format is easiest for further sd
           processing; use MS for CASA imaging.
           If ASCII, then will append some stuff to
           the outfile name
overwrite -- overwrite the output file if already exists
  options: (bool) True, False
  default: False
  WARNING: if outform='ASCII', this parameter is ignored

DESCRIPTION:

Task `sdcoadd` merges multiple single dish spectral data given by a list of spectral data file names in any of the following formats, ASAP, MS2, and SDFITS. The units of line flux, the units of spectral axis, frame, and doppler are assumed to be those of the first one in the `sdfilelist` if not specified. The `timeaverage` and `polaverage` are used to perform time and polarization averaging over scans on the merged scantable to obtained co-added spectra before saving to a file on disk.
A.2.1.6 sdflag

Keyword arguments:

sdfile -- name of input SD dataset

scanlist -- list of scan numbers to process
default: [] (use all scans)
example: [21,22,23,24]
this selection is in addition to field and iflist

field -- selection string for selecting scans by name
default: '' (no name selection)
example: 'FLS3a*' this selection is in addition to scanlist and iflist

iflist -- list of IF id numbers to select
default: [] (use all IFs)
example: [15] this selection is in addition to scanlist and field

pollist -- list of polarization id numbers to select
default: [] (use all polarizations)
example: [1] this selection is in addition to scanlist, field, and iflist

maskflag -- list of mask regions to apply flag/unflag
default: [] (entire spectrum)
example: [[1000,3000],[5000,7000]]

flagmode -- flag mode
default: 'flag'
options: 'flag','unflag','restore'
in 'restore' mode, a history of flagging is displayed and current flag state is returned

outfile -- Name of output file
default: '<sdfile>_f'

outform -- format of output file
options: 'ASCII','SDFITS','MS','ASAP'
default: 'ASAP'
example: the ASAP format is easiest for further sd processing; use MS for CASA imaging.

overwrite -- overwrite the output file if already exists
options: (bool) True,False
default: False
WARNING: if outform='ASCII', this parameter is ignored

plotlevel -- control for plotting of results
options: (int) 0=none, 1=some, 2=more, <0=hardcopy
default: 0 (no plotting)
example: plotlevel<0 as abs(plotlevel), e.g.
   -1 => hardcopy of final plot (will be named
       <outfile>_flag.eps)
WARNING: be careful plotting in fsof mode!

Returns: Current values of maskflag for each spectrum as a list,
          only if flagmode is set to 'restore'. Note that the
          'restore' mode refers scanlist, iflist, and pollist.

DESCRIPTION:

Task sdflag performs simple channel based flagging on spectra. The flag regions in channels
can be specified in maskflag. This is not interactive flagging. If plotlevel>=1, the task asks
you if you really apply the flags before it is actually written to the data with a plot indicating
flagged regions. The flags are not written to the current (input) datasets unless outfile='none'.
Flagged regions (or values of flag masks already applied) of the input data can be listed by setting
flagmode='restore'. It will print out a summary on the screen and returns maskflag values for
each spectrum as a list. Please note that this task is still experimental.

A.2.1.7  sfit

Keyword arguments:

sdfile -- name of input SD dataset
    default: none - must input file name
    example: 'mysd.asap'
See sdcal for allowed formats.

fluxunit -- units for line flux
    options: (str) 'K','Jy',''
    default: '' (keep current fluxunit)
WARNING: For GBT data, see description below.

>>> fluxunit expandable parameter

telelescopeparm -- the telescope characteristics
    options: (str) name or (list) list of gain info
    default: '' (none set)
    example: if telescopeparm='', it tries to get the telescope
             name from the data.
             Full antenna parameters (diameter,ap.eff.) known
to ASAP are
             'ATPKSMB', 'ATPKSHOH', 'ATMOPRA', 'DSS-43',
             'CEDUNA','HOBART'. For GBT, it fixes default fluxunit
to 'K' first then convert to a new fluxunit.
    telescopeparm=[104.9,0.43] diameter(m), ap.eff.
telescopeparm=[0.743] gain in Jy/K

specunit -- units for spectral axis
  options: (str) 'channel', 'km/s', 'GHz', 'MHz', 'kHz', 'Hz', ''
  default: '' (=current)

frame -- frequency frame for spectral axis
  options: (str) 'LSRK', 'REST', 'TOPO', 'LSRD', 'BARY',
            'GEO', 'GALACTO', 'LGROUP', 'CMB'
  default: currently set frame in scantable

WARNING: frame='REST' not yet implemented

doppler -- doppler mode
  options: (str) 'RADIO', 'OPTICAL', 'Z', 'BETA', 'GAMMA'
  default: currently set doppler in scantable

scanlist -- list of scan numbers to process
  default: [] (use all scans)
  example: [21, 22, 23, 24]

field -- selection string for selecting scans by name
  default: '' (no name selection)
  example: 'FLS3a*'  
            this selection is in addition to scanlist
            and iflist

iflist -- list of IF id numbers to select
  default: [] (use all IFs)
  example: [15]

pollist -- list of polarization id numbers to select
  default: [] (use all polarizations)
  example: [1]

fitmode -- mode for fitting
  options: (str) 'list', 'auto'
  default: 'auto'
  example: 'list' will use maskline to define regions to
           fit for lines with nfit in each
           'auto' will use the linefinder to fit for lines
           using the following parameters

>>> fitmode expandable parameters

thresh -- S/N threshold for linefinder
  default: 5
  example: a single channel S/N ratio above which the channel
           is considered to be a detection

min_nchan -- minimum number of consecutive channels for linefinder
  default: 3
  example: minimum number of consecutive channels required to
           pass threshold
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

avg_limit -- channel averaging for broad lines
default: 4
example: a number of consecutive channels not greater than
this parameter can be averaged to search for broad
lines

box_size -- running mean box size
default: 0.2
example: a running mean box size specified as a fraction
of the total spectrum length

default: 0
example: [1000] drops 1000 channels at beginning AND end
[1000,500] drops 1000 from beginning and 500 from
end

Note: For bad baselines threshold should be increased,
and avg_limit decreased (or even switched off completely by
setting this parameter to 1) to avoid detecting baseline
undulations instead of real lines.

Note: For bad baselines threshold should be increased,
and avg_limit decreased (or even switched off completely by
setting this parameter to 1) to avoid detecting baseline
undulations instead of real lines.

maskline -- list of mask regions to INCLUDE in LINE fitting
default: all
example: maskline=[[3900,4300]] for a single region, or
maskline=[[3900,4300],[5000,5400]] for two, etc.

invertmask -- invert mask (EXCLUDE masklist instead)
options: (bool) True, False
default: False
example: invertmask=True, then will make one region that is
the exclusion of the maskline regions

fitfile -- name of output file for fit results
default: no output fit file
example: 'mysd.fit'

overwrite -- overwrite the fitfile if already exists
options: (bool) True, False
default: False

plotlevel -- control for plotting of results
options: (int) 0=none, 1=some, 2=more
default: 0 (no plotting)
example: plotlevel=1 plots fit
plotlevel=2 plots fit and residual
no hardcopy available for fitter
WARNING: be careful plotting OTF data with lots of fields

-------------------------------------------------------------------
Returns a Python dictionary of line statistics
keys: 'peak','cent','fwhm','nfit'
example: each value is a list of lists with one list of
2 entries [fitvalue,error] per component.
e.g. xstat['peak']=[[234.9, 4.8],[234.2, 5.3]]
for 2 components.

DESCRIPTION:

Task sdfit is a basic line-fitter for single-dish spectra. It assumes that the spectra have been
calibrated in sdaverage or sdcal.

Furthermore, it assumes that any selection of scans, IFs, polarizations, and time and channel
averaging/smoothing has also already been done (in other sd tasks) as there are no controls for
these. Note that you can use sdsave to do selection, writing out a new scantable.

Note that multiple scans and IFs can in principle be handled, but we recommend that you use
scanlist, field, and iflist to give a single selection for each fit.

For complicated spectra, sdfit does not do a good job of "auto-guessing" the starting model for
the fit. We recommend you use sd.fitter in the toolkit which has more options, such as fixing
components in the fit and supplying starting guesses by hand.

See the sdaverage description for information on fluxunit conversion and the telescopeparm
parameter.

Beta Patch 4 New Features: The parameter overwrite is added to allow overwrite of output
fitfile.

A.2.1.8 sdlist

Keyword arguments:
sdfile -- name of input SD dataset
scanaverage -- average integrations within scans
    options: (bool) True,False
default: False
    example: if True, this happens in read-in
    For GBT, set False!
listfile -- Name of output file for summary list
default: "" (no output file)
    example: 'mysd_summary.txt'
overwrite -- overwrite the output file if already exists
    options: (bool) True,False
default: False
DESCRIPTION:

Task `sdlist` lists the scan summary of the dataset after importing as a scantable into ASAP. It will optionally output this summary as file.

Note that if your `PAGER` environment variable is set to 'less' and you have set the `verbose` ASAP environment variable to True (the default), then the screen version of the summary will page. You can disable this for `sdlist` by setting `sd.rcParams['verbose']=False` before running `sdlist`. Set it back afterward if you want lots of information.

A.2.1.9 `sdmath`

Keyword arguments:

`expr` -- Mathematical expression using scantables

`fluxunit` -- units for line flux
   options: 'K','Jy',''
   default: '' (keep current fluxunit)
   WARNING: For GBT data, see description below.

>>> fluxunit expandable parameter

`telescopeparm` -- the telescope characteristics
   options: (str) name or (list) list of gain info
   default: '' (none set)
   example: if telescopeparm='', it tries to get the telescope name from the data.
   Full antenna parameters (diameter,ap.eff.) known to ASAP are
   'ATPKSMB', 'ATPKSHOH', 'ATMOPRA', 'DSS-43', 'CEDUNA','HOBART'. For GBT, it fixes default fluxunit to 'K' first then convert to a new fluxunit.
   telescopeparm=[104.9,0.43] diameter(m), ap.eff.
   telescopeparm=[0.743] gain in Jy/K
   telescopeparm='FIX' to change default fluxunit
   see description below

`specunit` -- units for spectral axis
   options: (str) 'channel','km/s','GHz','MHz','kHz','Hz'
   default: '' (=current)
   example: this will be the units for masklist

`frame` -- frequency frame for spectral axis
   options: (str) 'LSRK','REST','TOPO','LSRD','BARY','GEO','GALACTO','LGROUP','CMB'
   default: currently set frame in scantable
   WARNING: frame='REST' not yet implemented

`doppler` -- doppler mode
   options: (str) 'RADIO','OPTICAL','Z','BETA','GAMMA'
default: currently set doppler in scantable

scanlist -- list of scan numbers to process
default: [] (use all scans)
exmple: [21,22,23,24]
this selection is in addition to field, iflist, and pollist

field -- selection string for selecting scans by name
default: '' (no name selection)
exmple: 'FLS3a*'
this selection is in addition to scanlist, iflist, and pollist

iflist -- list of IF id numbers to select
default: [] (use all IFs)
exmple: [15]
this selection is in addition to scanlist, field, and pollist

pollist -- list of polarization id numbers to select
default: [] (use all polarizations)
exmple: [1]
this selection is in addition to scanlist, field, and iflist

outfile -- Name of output file
default: '' (<sdfile>_cal)

outform -- format of output file
options: 'ASCII','SDFITS','MS','ASAP'
default: 'ASAP'
exmple: the ASAP format is easiest for further sd processing; use MS for CASA imaging.
If ASCII, then will append some stuff to the outfile name

overwritte -- overwrite the output file if already exists
options: (bool) True,False
default: False
WARNING: if outform='ASCII', this parameter is ignored

DESCRIPTION:

Task sdmath execute a mathematical expression for single dish spectra. The spectral data file can be any of the formats supported by ASAP (scantable, MS, rpfits, and SDFITS). In the expression, these file names should be put inside of single or double quotes.

The fluxunit, specunit, and frame can be set, otherwise, the current settings of the first spectral data in the expression are used. Other selections (e.g. scan No, . IF, Pol) also apply to all the spectral data in the expression, so if any of the data does not contains selection, the task will produce no output.

Example:
# do on-off/off calculation
expr='("orion_on_data.asap"-"orion_off_data.asap")/"orion_off_data.asap"
outfile='orion_cal.asap'
sdmath()

A.2.1.10 sdplot

Keyword arguments:
sdfile -- name of input SD dataset
fluxunit -- units for line flux
    options: 'K','Jy',''
    default: '' (keep current fluxunit)
    WARNING: For GBT data, see description below.
    >>> fluxunit expandable parameter
    telescopeparm -- the telescope characteristics
    options: (str) name or (list) list of gain info
    default: '' (none set)
    example: if telescopeparm='', it tries to get the telescope
              name from the data.
              Full antenna parameters (diameter,ap.eff.) known
              to ASAP are
              'ATPKSMB', 'ATPKSHOH', 'ATMOPRA', 'DSS-43',
              'CEDUNA','HOBART'. For GBT, it fixes default fluxunit
to 'K' first then convert to a new fluxunit.
    telescopeparm=[104.9,0.43] diameter(m), ap.eff.
    telescopeparm=[0.743] gain in Jy/K
    telescopeparm='FIX' to change default fluxunit
    see description below

specunit -- units for spectral axis
    options: (str) 'channel','km/s','GHz','MHz','kHz','Hz'
    default: '' (current)
    example: this will be the units for masklist

restfreq -- rest frequency used for specunit='km/s'
    default: '' (use current setting)
    example: 4.6e10 (float value), '46GHz' (string with unit)

frame -- frequency frame for spectral axis
    options: (str) 'LSRK','REST','TOPO','LSRD','BARY',
              'GEO','GALACTO','LGROUP','CMB'
    default: currently set frame in scantable
    WARNING: frame='REST' not yet implemented

doppler -- doppler mode
    options: (str) 'RADIO','OPTICAL','Z','BETA','GAMMA'
default: currently set doppler in scantable

scanlist -- list of scan numbers to process
default: [] (use all scans)
example: [21,22,23,24]
    this selection is in addition to field
    iflist and pollist

field -- selection string for selecting scans by name
default: '' (no name selection)
example: 'FLS3a*'  
    this selection is in addition to scanlist
    iflist and pollist

iflist -- list of IF id numbers to select
default: [] (use all IFs)
example: [15]
    this selection is in addition to scanlist
    field and pollist

pollist -- list of polarization id numbers to select
default: [] (use all polarizations)
example: [1]
    this selection is in addition to scanlist,
    field, and iflist

scanaverage -- average integs within scans
options: (bool) True,False
default: False

timeaverage -- average times for multiple scan cycles
options: (bool) True,False
default: False
    example: if True, this happens after calibration

    >>>timeaverage expandable parameter
    tweight -- weighting for time average
    options: 'none'
               'var'  (1/var(spec) weighted)
               'tsys' (1/Tsys**2 weighted)
               'tint'  (integration time weighted)
               'tintsys'  (Tint/Tsys**2)
               'median' ( median averaging)
    default: 'none'

polaverage -- average polarizations
options: (bool) True,False
default: False

    >>>polaverage expandable parameter
    pweight -- weighting for polarization average
    options: 'none'
               'var'  (1/var(spec) weighted)
               'tsys' (1/Tsys**2 weighted)
kernel -- type of spectral smoothing
  options: 'hanning', 'gaussian', 'boxcar', 'none'
  default: 'none'
>>> kernel expandable parameter
kwidth -- width of spectral smoothing kernel
  options: (int) in channels
  default: 5
  example: 5 or 10 seem to be popular for boxcar
           ignored for hanning (fixed at 5 chans)
           (0 will turn off gaussian or boxcar)

plottype -- type of plot
  options: 'spectra', 'totalpower', 'pointing', 'azel'
  default: 'spectra'

stack -- code for stacking on single plot for spectral plotting
  options: 'p', 'b', 'i', 't', 's' or
           'pol', 'beam', 'if', 'time', 'scan'
  default: 'p'
  example: maximum of 25 stacked spectra
           stack by pol, beam, if, time, scan

panel -- code for splitting into multiple panels for spectral plotting
  options: 'p', 'b', 'i', 't', 's' or
           'pol', 'beam', 'if', 'time', 'scan'
  default: 'i'
  example: maximum of 25 panels
           panel by pol, beam, if, time, scan

flrange -- range for flux axis of plot for spectral plotting
  options: (list) [min, max]
  default: [] (full range)
  example: flrange=[-0.1, 2.0] if 'K'
           assumes current fluxunit

sprange -- range for spectral axis of plot
  options: (list) [min, max]
  default: [] (full range)
  example: sprange=[42.1, 42.5] if 'GHz'
           assumes current specunit

linecat -- control for line catalog plotting for spectral plotting
  options: (str) 'all', 'none' or by molecule
  default: 'none' (no lines plotted)
  example: linecat='SiO' for SiO lines
           linecat='*OH' for alcohols
           uses sprange to limit catalog
WARNING: specunit must be in frequency (*Hz)
          to plot from the line catalog!
          and must be 'GHz' or 'MHz' to use
          sprange to limit catalog
linedop -- doppler offset for line catalog plotting (spectral plotting)
  options: (float) doppler velocity (km/s)
  default: 0.0
  example: linedop=-30.0

colormap -- the colours to be used for plot lines.
  default: None
  example: colormap="green red black cyan magenta" (html standard)
  colormap="g r k c m" (abbreviation)
  colormap="#008000 #00FFFF #FF0090" (RGB tuple)
  The plotter will cycle through these colours when lines are overlaid (stacking mode).

linestyles -- the linestyles to be used for plot lines.
  default: None
  example: linestyles="line dashed dotted dashdot dashdotdot dashdashdot".
  The plotter will cycle through these linestyles when lines are overlaid (stacking mode).
  WARNING: Linestyles can be specified only one color has been set.

linewidth -- width of plotted lines.
  default: None
  example: linewidth=1 (integer)
            linewidth=0.75 (double)

histogram -- plot histogram
  options: (bool) True, False
  default: False

plotfile -- file name for hardcopy output
  options: (str) filename.eps,.ps,.png
  default: '' (no hardcopy)
  example: 'specplot.eps','specplot.png'
  Note this autodetects the format from the suffix (.eps,.ps,.png).

overwrite -- overwrite the output file if already exists
  options: (bool) True,False
  default: False

DESCRIPTION:

Task sdplot displays single-dish spectra. It assumes that the spectra have been calibrated in sdcal. It does allow selection of scans, IFs, polarizations, and some time and channel averaging/smoothing options also, but does not write out this data.

*** Only apply to 'spectra' plottype ***

Some header information of the data are plotted at top. Note that colormap and linestyles cannot be controlled at a time. The 'linestyles' is ignored if both of them are specified. Some plot options, like annotation and changing titles, legends, fonts, and the like are not supported in this task. You should use sd.plotter from the ASAP toolkit directly for this.
This task uses the JPL line catalog as supplied by ASAP. If you wish to use a different catalog, or have it plot the line IDs from top or bottom (rather than alternating), then you will need to explore the sd toolkit also. See §A.3.9 for more information.

Note that multiple scans and IFs can in principle be handled through stacking and paneling, but this is fairly rudimentary at present and you have little control of what happens in individual panels. We recommend that you use scanlist, field, and iflist to give a single selection for each run.

After plotting, you can display a spectral value on a pop-up window along with mouse movement. Click the LEFT-mouse button over a spectrum to select it, and drag mouse in the panel to output its value at the x-position of mouse cursor. The selection is released when you release the mouse button.

The task sdplot adds an additional toolbar to ASAP plotter which has three buttons, 'spec value', 'statistics', and 'Quit'. When the 'spec value' button is pressed and activated, you can display a spectral value on the toolbar along with mouse movement. Click the LEFT-mouse button over a spectrum to select it, and drag mouse in the panel to output its value at the x-position of mouse cursor. The selection is released when you release the mouse button. When 'statistic' button is pressed and activated, you can get statistic values of a channel region selected by mouse. Select a rectangle region with LEFT/RIGHT-mouse to SELECT/EXCLUDE the channel region to calculate statistics for the all spectra plotted. The results are printed on the casapy console. Press 'Quit' button to close the plotter.

*** other plottype options ***

plottype='totalpower' is used to plot the total power data. and only plot option is amplitude versus data row number. plottype='azel' plots azimuth and elevation tracks of the source. plottype='pointing' plots antenna pointing. Currently most of the plotting parameters are ignored these modes.

See the sdaverage description for information on fluxunit conversion and the telescopeparm parameter.

WARNING: be careful plotting OTF (on-the-fly) mosaic data with lots of fields!

Beta Patch 4 New Features:

- The parameter, restfreq is added to set rest frequency when specunit='km/s is chosen
- Improvement on spectral value display feature is made
- Now you can specify the region interactively on the plot to get statistics of the region of the spectrum without launching sdstat

A.2.1.11 sdsave

Keyword arguments:

sdfile -- name of input SD dataset
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

**scanlist** -- list of to process
default: [] (use all scans)
example: [21, 22, 23, 24]
this selection is in addition to field, iflist, and pollist

**field** -- selection string for selecting scans by name
default: '' (no name selection)
example: 'FLS3a*'
this selection is in addition to scanlist, iflist, and pollist

**iflist** -- list of IF id numbers to select
default: [] (use all IFs)
example: [15]
this selection is in addition to scanlist, field, and pollist

**pollist** -- list of polarization id numbers to select
default: [] (use all polarizations)
example: [1]
this selection is in addition to scanlist, field, and iflist

**scanaverage** -- average integrations within scans
options: (bool) True,False
default: False
eexample: if True, average integrations before it is saved

**timeaverage** -- average times for multiple scan cycles
options: (bool) True,False
default: False
>>timeaverage expandable parameter

**tweight** -- weighting for time average
options: 'none'
  'var' (1/var(spec) weighted)
  'tys' (1/Tsys**2 weighted)
  'tint' (integration time weighted)
  'tintsys' (Tint/Tsys**2)
  'median' (median averaging)
default: 'none'

**polaverage** -- average polarizations
options: (bool) True,False
default: False
>>polaverage expandable parameter

**pweight** -- weighting for polarization average
options: 'none'
  'var' (1/var(spec) weighted)
  'tys' (1/Tsys**2 weighted)
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

outfile -- name of output dataset
   default: ''
outform -- output data format
   default: 'ASAP'
   Options: 'ASAP', 'MS2', 'SDFITS', 'ASCII'
overwrite -- overwrite the output file if already exists
   options: (bool) True,False
   default: False
   WARNING: if outform='ASCII', this parameter is ignored

DESCRIPTION:

Task sdsave writes the single dish data to a disk file in specified format (ASAP, MS2, SDFITS, ASCII). It is possible to save the subset of the data by selecting scan numbers, IF ids and field names. The ASAP (scantable) format is recommended for further analysis using sd tool. For further imaging using imager, save the data to the Measurement Set (MS2).

A.2.1.12 sdscale

Keyword arguments:
sdfile -- name of input SD dataset
factor -- scaling factor
   default: 1 (no scaling)
scaletsys -- scaling of associated Tsys
   default: False
outfile -- output file name
   outfile=’’ will write the data to a file named,
   <sdfile>_scaled<factor>
   default: ’’
overwrite -- overwrite the output file if already exists
   options: (bool) True,False
   default: False

DESCRIPTION:

Task sdscale performs scaling of single-dish spectra. By setting scaletsys = True, associated Tsys is also scaled. Tsys information are written into the file 'sdscale.log' as well as they are displayed in the terminal window. The infile can be any of ASAP, MS, SDFITS, or RPFITS format. If outfile name is given or outfile=’’(default), the scaled data is written to a new file with the same format as the input data (Note: in case of the RPFITS format input data, it will be written to SDFITS format).

A.2.1.13 sdstat

Keyword arguments:
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

**sdfile** -- name of input SD dataset

    default: none - must input file name
    example: 'mysd.asap'

    See sdcal for allowed formats.

**fluxunit** -- units for line flux

    options: (str) 'K','Jy',''
    default: '' (keep current fluxunit)

    WARNING: For GBT data, see description below.

**telescopeparm** -- the telescope characteristics

    options: (str) name or (list) list of gain info
    default: '' (none set)

    example: if telescopeparm='', it tries to get the telescope
    name from the data.

    Full antenna parameters (diameter,ap.eff.) known
    to ASAP are
    'ATPKSMB', 'ATPKSHOH', 'ATMOPRA', 'DSS-43',
    'CEDUNA','HOBART'. For GBT, it fixes default fluxunit
    to 'K' first then convert to a new fluxunit.

    telescopeparm=[104.9,0.43] diameter(m), ap.eff.

    telescopeparm=[0.743] gain in Jy/K

    telescopeparm='FIX' to change default fluxunit

    see description below

**specunit** -- units for spectral axis

    options: (str) 'channel','km/s','GHz','MHz','kHz','Hz',''
    default: '' (=current)

**frame** -- frequency frame for spectral axis

    options: (str) 'LSRK','REST','TOPO','LSRD','BARY',
    'GEO','GALACTO','LGROUP','CMB'

    default: currently set frame in scantable

    WARNING: frame='REST' not yet implemented

**doppler** -- doppler mode

    options: (str) 'RADIO','OPTICAL','Z','BETA','GAMMA'

    default: currently set doppler in scantable

**scanlist** -- list of scan numbers to process

    default: [] (use all scans)

    example: [21,22,23,24]

**field** -- selection string for selecting scans by name

    default: '' (no name selection)

    example: 'FLS3a*'

    this selection is in addition to scanlist
    iflist, and pollist

**iflist** -- list of IF id numbers to select

    default: [] (use all IFs)
example: [15]
    this selection is in addition to field, scanlist
    and pollist
pollist -- list of polarization id numbers to select
default: [] (use all pols)
example: [1]
    this selection is in addition to field, scanlist
    and iflist
masklist -- list of mask regions to INCLUDE in stats
default: [] (whole spectrum)
example: [4000,4500] for one region
        [[1000,3000],[5000,7000]]
    these must be pairs of [lo,hi] boundaries
invertmask -- invert mask (EXCLUDE masklist instead)
options: (bool) True,False
default: false
    interactive -- determines interactive masking
    options: (bool) True,False
default: False
    example: interactive=True allows adding and deleting mask
        regions by drawing rectangles on the plot with mouse.
        Draw a rectangle with LEFT-mouse to ADD the region to
        the mask and with RIGHT-mouse to DELETE the region.
statfile -- name of output file for line statistics
default: '' (no output statistics file)
example: 'stat.txt'
overwrite -- overwrite the statistics file if already exists
options: (bool) True,False
default: False
-------------------------------

Returns: a Python dictionary of line statistics
keys: 'rms','stddev','max','max_abscissa', 'min',
      'min_abscissa', 'sum','median','mean',
      'totint','eqw',
example: xstat=sdstat(); print "rms = ",xstat['rms']
    these can be used for testing in scripts or
    for regression

    'totint' is the integrated intensity (sum*dx)
where dx is the abscissa interval in 'specunit'.
    'eqw' is equivalent width (totint/mag) where mag
is either max or min depending on which has
    greater magnitude.
Note that both 'totint' and 'eqw' are quantities
(dictionaries) with 'unit' and 'value'.

APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

DESCRIPTION:

Task **sdstat** computes basic statistics (rms, mean, median, sum) for single-dish spectra. It assumes that the spectra have been calibrated. Furthermore, it assumes that any time and channel averaging/-smoothing has also already been done as there are no controls for these. Note that you can run **sdcal** with **calmode='none'** and do selection, writing out a new scantable. The calculated statistics are written into a file specified by **statfile**. Interactive mask specification is possible with **interactive=True**. Integrated intensity will be shown on the screen and will be included in the saved statfile (but not yet available in the returned dictionary).

Note that multiple scans and IFs can in principle be handled, but we recommend that you use **scanlist**, **field**, **iflist**, and **pollist** to give a single selection for each run.

See the **sdcal** description for information on **fluxunit** conversion and the **telescopeparm** parameter.

**WARNING:** If you do have multiple scantable rows, then **xstat** values will be lists.

**Beta Patch 4 New Features:**

- The total intensity of spectrum and the abscissa (channel, frequency, or velocity) of maximum and minimum intensities are calculated and returned with their units. You can refer to the total intensities with key 'totint' in the returned dictionary, while the key 'max_abscissa' and 'min_abscissa' refer to the abscissa of maximum and minimum, respectively.
- The equivalent width is also returned with it's unit in returned dictionary
- The **overwrite** is added to allow overwrite of statfile.

**A.2.1.14 sdtpimaging**

Keyword arguments:

**sdfile** -- name of input SD (MS) dataset

**calmode** -- calibration mode (currently only baseline subtraction)
  - options: 'baseline', 'none'
  - default: 'none'
  - example: choose mode 'none' if you have already calibrated and want to do plotting nd/or imaging

>>> calmode='baseline' expandable parameters

**masklist** -- mask in numbers of rows from each edge of each scan to be included for baseline fitting
  - default: none
  - example: [30,30] or [30]
used first 30 rows and last 30 rows of each scan for the baseline

blpoly -- polynomial order for the baseline fit
default: 1

flaglist -- list of scan numbers to flag (ranges can be accepted)
default: [] (use all scans)
example: [[0,3],80]
flag the scan range [0,3] = [0,1,2,3] and scan 80

antenna -- select data based on antenna name(s) or id(s) in string
default: '' (use all antennas)
example: '0,1', 'DV01'
WARNING: currently baseline subtraction properly only one of the antennas.

stokes -- select data based on stokes or polarization type
default: '' (use all polarizations)
example: 'XX'

createimage -- do imaging?
default: False

>>> createimage=True expandable parameters

imagename -- output image name
default: none
example: 'mySDimage.im'

imsiz e -- x and y image size in pixels, symmetric for single value
default: [256,256]
example: imsize=200 (equivalent to [200,200])

cell -- x and y cell size. default unit arcmin
default: '1.0arcmin'
example: cell=['0.2arcmin', 0.2arcmin']

```
cell='0.2arcmin' (equivalent to example above)
```

phasecenter -- image phase center: direction measure or fieldid
default: 0
example: 'J2000 13h44m00 -17d02m00', 'AZEL -123d48m29 15d41m41'

ephemsrccname -- ephemeris source name to proper shifting to center on the moving source for imaging
default: ''
example: 'moon'

plotlevel -- control for plotting of results
options: (int) 0=none, 1=some, 2=more, <0=hardcopy
default: 0 (no plotting)
example: plotlevel<0 as abs(plotlevel), e.g.
-1: hardcopy plot (will be named <sdfile>_scans.eps)
 1: plot raw data, calibrated data (for calmode='baseline')
plot raw or if exist calibrated data (for calmode='none')
2: plot raw data, progressively display baseline fitting for each scan, and final calibrated data (for calmode='baseline')

DESCRIPTION:
Task sdtpimaging performs data selection, calibration, and imaging for single-dish totalpower raster scan data. This is a still experimental task made to work for the data taken at the ALMA Testing Facility (ATF) and OSF. Currently, this task directly accesses the Measurement Set data because of the data access efficiency. So it differs from other single-dish tasks that mostly operate on the ASAP scantable data format. By setting calmode='none', one can run sdtpimaging to plot the data (raw or calibrated, if exists) and further imaging by setting createimage=True. The calibration available at this moment is just a simple baseline subtraction for each scan. The fitted regions set by masklist are the common for all the scans. Selection of the antennas can be made by setting antenna ID(s) or antenna name(s) in string (e.g. '0', '0,1', 'DV01', etc.). For baseline subtraction, it currently works properly for a single antenna selection. So a separate sdtpimaging task needs to be run for each antenna. It currently assumes that the data has a single spw(=0) and fieldid(=0). By setting flaglist, one can set flag by scan numbers to be excluded from imaging. (Note: ‘scan numbers’ are determined from state id and related to SUB_SCAN column in STATE subtable and they are typically different from SCAN_NUMBER in MS.)

Beta Patch 4 New Feature: The parameter, stokes is added for selecting polarization.

A.2.2 Single Dish Analysis Use Cases With SDTasks

A.2.2.1 GBT Position Switched Data Analysis

As an example, the following illustrates the use of the SDtasks for the Orion data set, which contains the HCCCN line in one of its IFs. This walk-through contains comments about setting parameter values and some options during processing.

```
# ORION-S SDtasks Use Case
# Position-Switched data
# Version TT 2008-10-14 (updated)
# Version STM 2007-03-04
#
# This is a detailed walk-through
# for using the SDtasks on a
# test dataset.
#
import time
```
import os

# NOTE: you should have already run
# asap_init()
# to import the ASAP tools as sd.<tool>
# and the SDtasks
#
# This is the environment variable
# pointing to the head of the CASA
# tree that you are running
casapath=os.environ['AIPSPATH']

# This bit removes old versions of the output files
os.system('rm -rf sdusecase_orions* ')
#
# This is the path to the OrionS GBT ms in the data repository
datapath=casapath+’/data/regression/ATST5/OrionS/OrionS_rawACSmod’
#
# The following will remove old versions of the data and
# copy the data from the repository to your
# current directory. Comment this out if you already have it
# and don’t want to recopy
os.system('rm -rf OrionS_rawACSmod')
copystring='cp -r '+datapath+' .'
os.system(copystring)

# Now is the time to set some of the more useful
# ASAP environment parameters (the ones that the
# ASAP User Manual claims are in the .asaprc file).
# These are in the Python dictionary sd.rcParams
# You can see whats in it by typing:
#sd.rcParams
# One of them is the 'verbose' parameter which tells
# ASAP whether to spew lots of verbiage during processing
# or to keep quiet. The default is
#sd.rcParams['verbose']=True
# You can make ASAP run quietly (with only task output) with
#sd.rcParams['verbose']=False

# Another key one is to tell ASAP to save memory by
# going off the disk instead. The default is
#sd.rcParams['scantable.storage']='memory'
# but if you are on a machine with small memory, do
#sd.rcParams['scantable.storage']='disk'

# You can reset back to defaults with
#sd.rcdefaults

# ORION-S HC3N
# Position-Switched data
#
startTime=time.time()
startProc=time.clock()

# List data
#
# List the contents of the dataset
# First reset parameter defaults (safe)
default('sdlist')

# You can see its inputs with
#inp('sdlist')
# or just
#inp
# now that the defaults('sdlist') set the
# taskname='sdlist'
#
# Set the name of the GBT ms file
sdfile = 'OrionS_rawACSmod'

# Set an output file in case we want to

# The HC3N and CH3OH lines are in IFs 0 and 2 respectively
# of scans 20,21,22,23. We will pull these out in our
calibration.

############################
# Calibrate data
############################
# We will use the sdcal task to calibrate the data.
# Set the defaults
default(’sdcal’)

# You can see the inputs with
#inp

# Set our sdfile (which would have been set from our run of
# sdlist if we were not cautious and reset defaults).
sdfile = ’OrionS_rawACSmod’
fluxunit = ’K’

# Lets leave the spectral axis in channels for now
specunit = ’channel’

# This is position-switched data so we tell sdcal this
calmode = 'ps'

# For GBT data, it is safest to not have scantable pre-average
# integrations within scans.
average = True
scanaverage = False

# We do want sdcal to average up scans and polarization after
# calibration however. The averaging of scans are weighted by
# integration time and Tsys, and the averaging of polarization
# by Tsys.
timeaverage = True
tweight = 'tintsys'
polaverage = True
pweight = 'tsys'

# Do an atmospheric optical depth (attenuation) correction
# Input the zenith optical depth at 43 GHz
tau = 0.09

# Select our scans and IFs (for HC3N)
scanlist = [20,21,22,23]
iflist = [0]

# We do not require selection by field name (they are all
# the same except for on and off)
field = ''

# We will do some spectral smoothing
# For this demo we will use boxcar smoothing rather than
# the default
#kernel='hanning'
kernel = 'boxcar'
kwidth = 5

# We wish to fit out a baseline from the spectrum
# The GBT has particularly nasty baselines :(.
# We will let ASAP use auto_poly_baseline mode
# but tell it to drop the 1000 edge channels from
# the beginning and end of the spectrum.
# A 2nd-order polynomial will suffice for this test.
# You might try higher orders for fun.
blmode = 'auto'
blpoly = 2
edge = [1000]
# We will not give it regions as an input mask
# though you could, with something like
# masklist=[[1000,3000],[5000,7000]]
masklist = []

# By default, we will not get plots in sdcal (but
# can make them using sdplot).
plotlevel = 0
# But if you wish to see a final spectrum, set
# plotlevel = 1
# or even
# plotlevel = 2
# to see intermediate plots and baselining output.

# Now we give the name for the output file
outfile = 'sdusecase_orions_HC3N.asap'

# We will write it out in ASAP scantable format
outform = 'asap'

# You can look at the inputs with
# inp

# Before running, lets save the inputs in case we want
# to come back and re-run the calibration.
saveinputs('sdcal','sdcal.orions.save')
# These can be recovered by
# execfile 'sdcal.orions.save'

# We are ready to calibrate
sdcal()

# Note that after the task ran, it produced a file
# sdcal.last which contains the inputs from the last
# run of the task (all tasks do this). You can recover
# this (any time before sdcal is run again) with
# execfile 'sdcal.last'

# List data
# List the contents of the calibrated dataset
# Set the input to the just created file
sdfile = outfile
listfile = ''
sdlist()

# You should see:

#  'rms': 0.35585442185401917,
#  'stddev': 0.27503398060798645,
#  'sum': 68.135047912597656}

# of particular interest are the max value
print "The on-line maximum = %5.3f K" % (line_stat['max'])
# which gives
# The on-line maximum = 0.929 K

# and the estimated equivalent width (in channels)
# which is the sum/max
print "The estimated equivalent width = %5.1f channels" %
    (line_stat['eqw'])
# which gives
# The estimated equivalent width = 73.3 channels

# Line Fitting

# Line Fitting
# Now we are ready to do some line fitting
# Default the parameters
default('sdfit')

# Set our input file
sdfile = 'sdasecase_orions_hc3n.asap'

# Stick to defaults
# fluxunit = 'K', specunit = 'channel'
fluxunit = ''
specunit = ''

# We will try auto-fitting first
fitmode = 'auto'
# A single Gaussian
nfit = [1]
# Leave the auto-parameters to their defaults for
# now, except ignore the edge channels
defac = [1000]

# Lets see a plot while doing this
plotlevel = 1

# Save the fit output in a file
fitfile = 'sdasecase_orions_hc3n.fit'

# Go ahead and do the fit
fit_stat = sdfit()

# If you had verbose mode on, you probably saw something
# like:
#
# 0: peak = 0.81 K, centre = 4091.041 channel, FWHM = 72.900 channel
# area = 62.918 K channel
#

# The fit is output in the dictionary
fit_stat

# {'cent': [[4091.04052734375, 0.72398632764816284]],
# 'fwhm': [[72.899894714355469, 1.7048574686050415]],
# 'nfit': 1,
# 'peak': [[0.8108044266700746, 0.016420882195234299]]}
# So you can write them out or test them:
print "The line-fit parameters were:"
print " maximum = %6.3f +/- %6.3f K" %\n (fit_stat['peak'][0][0],fit_stat['peak'][0][1])
print " center = %6.1f +/- %6.1f channels" %\n (fit_stat['cent'][0][0],fit_stat['cent'][0][1])
print " FWHM = %6.2f +/- %6.2f channels" %\n (fit_stat['fwhm'][0][0],fit_stat['fwhm'][0][1])
#
# Which gives:
# The line-fit parameters were:
# maximum = 0.811 +/- 0.016 K
# center = 4091.0 +/- 0.7 channels
# FWHM = 72.90 +/- 1.70 channels

# We can do the fit in km/s also
specunit = 'km/s'
# For some reason we need to help it along with a mask
maskline = [-50,0]

fitfile = 'sdusecase_orions_hc3n_kms.fit'
fit_stat_kms = sdfit()
# Should give (if in verbose mode)
# 0: peak = 0.811 K, centre = -27.134 km/s, FWHM = 2.933 km/s
# area = 2.531 K km/s
#
# with
fit_stat_kms
# giving
# {'cent': [[-27.133651733398438, 0.016480101272463799]],
# 'fwhm': [[2.93294358253479, 0.038807671517133713]],
# 'nfit': 1,
# 'peak': [[0.81080895662307739, 0.002909494414925575]]}

print "The line-fit parameters were:"
print " maximum = %6.3f +/- %6.3f K" %\n (fit_stat_kms['peak'][0][0],fit_stat_kms['peak'][0][1])
print " center = %6.2f +/- %6.2f km/s" %\n (fit_stat_kms['cent'][0][0],fit_stat_kms['cent'][0][1])
print " FWHM = %6.4f +/- %6.4f km/s" %\n (fit_stat_kms['fwhm'][0][0],fit_stat_kms['fwhm'][0][1])
The line-fit parameters were:

- maximum = 0.811 +/- 0.009 K
- center = -27.13 +/- 0.02 km/s
- FWHM = 2.9329 +/- 0.0388 km/s

A.2.2.2 Imaging of Total Power Raster Scans

This example illustrates the use of \texttt{sdtpimaging} for the total power raster scans of the Moon taken at ATF.

# load single dish module
# asap_init()

# The data used here (uid___X1e1_X3197_X1.ms) is the total power raster scans of the Moon taken at ATF (with both antennas).
# It is in MS format which was converted from the ASDM format.

# Do data plotting only
default(sdtpimaging)
inp()
plotlevel=2
# select antenna 1 (Vertex antenna)
antenna='1'
sdfile='uid___X1e1_X3197_X1.ms'
sdtpimaging()

# Now, rerun sdtpimaging to do actual data reduction (applying baseline subtraction from each scan, and then do imaging).
# Do baseline subtraction
calmode='baseline'
masklist=[30] # use 30 data points from each end of scan for fitting
# Do imaging
createimage=True
imagename='moon.im'
imagesize=[200,200]
cell=[0.2] # in arcmin
phasecenter='AZEL 187d54m22s 41d03m0s'
Figure A.2: Total power data display using `sdtpimaging`, with `calmode='baseline'`. The top panel shows uncalibrated data versus row numbers. The middle panel shows baseline fitting of each scan (only shown here the last scan). The bottom panel shows the calibrated (baseline subtracted) data.

```python
ephemsrcname='moon' # specify ephemeris source name (can be omitted)
plotlevel=1
#plotlevel=2 to see progress of each fitting
sdtpimaging()
```

### A.3 Using The ASAP Toolkit Within CASA

ASAP is included with the CASA installation/build. It is not loaded upon start-up, however, and must be imported as a standard Python package. A convenience function exists for importing
ASAP along with a set of prototype tasks for single dish analysis:

CASA <1>: asap_init

Once this is done, all of the ASAP functionality is now under the Python 'sd' tool. **Note:** This means that if you are following the ASAP cookbook or documentation, all of the commands should be invoked with a 'sd.' before the native ASAP command.

The ASAP interface is essentially the same as that of the CASA toolkit, that is, there are groups of functionality (aka tools) which have the ability to operate on your data. Type:

CASA <4>: sd.<TAB>

<table>

</tbody>
</table>

...to see the list of tools.

In particular, the following are essential for most reduction sessions:

- **sd.scantable** - the data structure for ASAP and the core methods for manipulating the data; allows importing data, making data selections, basic operations (averaging, baselines, etc) and setting data characteristics (e.g., frequencies, etc).

- **sd.selector** - selects a subset of data for subsequent operations

- **sd.fitter** - fit data
• sd.plotter - plotting facilities (uses matplotlib)

The scantable functions are used most often and can be applied to both the initial scantable and to any spectrum from that scan table. Type

    sd.scantable.<TAB>

(under TAB completion) to see the full list.

### A.3.1 Environment Variables

The asaprc environment variables are stored in the Python dictionary sd.rcParams in CASA. This contains a number of parameters that control how ASAP runs, for both tools and tasks. You can see what these are set to by typing at the CASA prompt:

```python
CASA <2>: sd.rcParams
Out[2]:
{'insitu': True,
 'plotter.colours': '',
 'plotter.decimate': False,
 'plotter.ganged': True,
 'plotter.gui': True,
 'plotter.histogram': False,
 'plotter.linestyles': '',
 'plotter.panelling': 's',
 'plotter.papertype': 'A4',
 'plotter.stacking': 'p',
 'scantable.autoaverage': True,
 'scantable.freqframe': 'LSRK',
 'scantable.save': 'ASAP',
 'scantable.storage': 'memory',
 'scantable.verbosesummary': False,
 'useplotter': True,
 'verbose': True}
```

The use of these parameters is described in detail in the ASAP Users Guide.

You can also change these parameters through the sd.rc function. The use of this is described in help sd.rc:

```python
CASA <3>: help(sd.rc)
Help on function rc in module asap:

rc(group, **kwargs)
    Set the current rc params. Group is the grouping for the rc, eg
    for scantable.save the group is 'scantable', for plotter.stacking, the
    group is 'plotter', and so on. kwargs is a list of attribute
name/value pairs, eg

rc('scantable', save='SDFITS')

sets the current rc params and is equivalent to

rcParams['scantable.save'] = 'SDFITS'

Use rcdefaults to restore the default rc params after changes.

A.3.2 Import

Data can be loaded into ASAP by using the scantable function which will read a variety of recognized formats (RPFITS, varieties of SDFITS, the CASA Measurement Set, and NRO OTF data format). For example:

CASA <1>: scans = sd.scantable('OrionS_rawACSmod', average=False)
Importing OrionS_rawACSmod...

The following are some cautions when using this import feature.

- It is important to use the average=False parameter setting as the calibration routines supporting GBT data require all of the individual times and phases.

- GBT data may need some pre-processing prior to using ASAP. In particular, the program which converts GBT raw data into CASA Measurement Sets tends to proliferate the number of spectral windows due to shifts in the tracking frequency; this is being worked on by GBT staff. In addition, GBT SDFITS is currently not readable by ASAP (in progress).

- The Measurement Set to scantable conversion is able to deduce the reference and source data and assigns an 'r' to the reference data to comply with the ASAP conventions.

- GBT observing modes are identifiable in scantable in the name assignment: position switched ('ps'), Nod ('nod'), and frequency switched ('fs'). These are combined with the reference data assignment. (For example, the reference data taken in position switched mode observation are assigned as 'psr'.)

- It is possible to read the ATF interferometric data as a single dish data to further examine it using ASAP Toolkit and the SD tasks. The usage is the same as importing single dish data (e.g. s=sd.scantable(your_ATF_synthesis_ms, 'False') ). It is still experimental and limited to the data obtained with the two-element synthesis data.

- Importing of Nobeyama Radio Observatory (NRO) OTF data is now available. However, it is still experimental and only tested to work from toolkit level.

Use the summary function to examine the data and get basic information:
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

CASA <8>: scans.summary()

Scan Table Summary

Beams: 1

A.3.3 Scantable Manipulation

Within ASAP, data is stored in a **scantable**, which holds all of the observational information and provides functionality to manipulate the data and information. The building block of a **scantable** is an integration which is a single row of a scantable. Each row contains just one spectrum for each beam, IF and polarization.

Once you have a **scantable** in ASAP, you can select a subset of the data based on scan numbers, sources, or types of scan; note that each of these selections returns a new ‘scantable’ with all of the underlying functionality:

- `CASA <5>: scan27=scans.get_scan(27) # Get the 27th scan`
- `CASA <6>: scans20to24=scans.get_scan(range(20,25)) # Get scans 20 - 24`
- `CASA <7>: scans_on=scans.get_scan('*_ps') # Get ps scans on source`
- `CASA <8>: scansOrion=scans.get_scan('Ori*') # Get all Orion scans`

To copy a scantable, do:

- `CASA <15>: ss=scans.copy()`

A.3.3.1 Data Selection

In addition to the basic data selection above, data can be selected based on IF, beam, polarization, scan number as well as values such as Tsys. To make a selection you create a **selector** object which you then define with various selection functions, e.g.,
sel = sd.selector()  # initialize a selector object
# sel.<TAB> will list all options
sel.set_ifs(0)       # select only the first IF of the data
scans.set_selection(sel)  # apply the selection to the data
print scans           # shows just the first IF

A.3.3.2 State Information

Some properties of a scantable apply to all of the data, such as example, spectral units, frequency frame, or Doppler type. This information can be set using the scantable_set_xxxx_methods. These are currently:

CASA <1>: sd.scantable.set_<TAB>
sd.scantable.set_dirframe   sd.scantable.set_fluxunit   sd.scantable.set_restfreqs
sd.scantable.set_doppler   sd.scantable.set_freqframe   sd.scantable.set_selection
sd.scantable.set_feedtype  sd.scantable.set_instrument  sd.scantable.set_unit

For example, sd.scantable.set_fluxunit sets the default units that describe the flux axis:

scans.set_fluxunit('K')  # Set the flux unit for data to Kelvin

Choices are 'K' or 'Jy'. Note: the scantable.set_fluxunit function only changes the name of the current fluxunit. To change fluxunits, use scantable.convert_flux as described in §[A.3.4.2] instead (currently you need to do some gymnastics for non-AT telescopes).

Use sd.scantable.set_unit to set the units to be used on the spectral axis:

scans.set_unit('GHz')    # Use GHZ as the spectral axis for plots

The choices for the units are 'km/s', 'channel', or '*Hz' (e.g. 'GHz', 'MHz', 'kHz', 'Hz'). This does the proper conversion using the current frame and Doppler reference as can be seen when the spectrum is plotted.

You can use sd.scantable.set_freqframe to set the frame in which the frequency (spectral) axis is defined:

CASA <2>: help(sd.scantable.set_freqframe)
Help on method set_freqframe in module asap.scantable:

set_freqframe(self, frame=None) unbound asap.scantable.scantable method
    Set the frame type of the Spectral Axis.
    Parameters:
        frame: an optional frame type, default 'LSRK'. Valid frames are:
            'REST', 'TOPO', 'LSRD', 'LSRK', 'BARY',
            'GEO', 'GALACTO', 'LGROUP', 'CMB'
    Examples:
        scan.set_freqframe('BARY')
The most useful choices here are frame = 'LSRK' (the default for the function) and frame = 'TOPO' (what the GBT actually observes in). Note that the 'REST' option is not yet available. The Doppler frame is set with sd.scantable.set_doppler:

CASA <3>: help(sd.scantable.set_doppler)
Help on method set_doppler in module asap.scantable:

```
sd.scantable.set_doppler(self, doppler='RADIO') unbound asap.scantable.scantable method
   Set the doppler for all following operations on this scantable.
   Parameters:
      doppler: One of 'RADIO', 'OPTICAL', 'Z', 'BETA', 'GAMMA'
```

Finally, there are a number of functions to query the state of the scantable. These can be found in the usual way:

CASA <4>: sd.scantable.get<TAB>
```
sd.scantable.get_abcissa      sd.scantable.get_restfreqs      sd.scantable.getbeamnos
sd.scantable.get_azimuth      sd.scantable.get_scan            sd.scantable.getcycle
sd.scantable.get_column_names sd.scantable.get_selection        sd.scantable.getif
sd.scantable.get_direction    sd.scantable.get_sourcename        sd.scantable.getifnos
sd.scantable.get_elevation    sd.scantable.get_time             sd.scantable.getpol
sd.scantable.get_fit          sd.scantable.get_tsys             sd.scantable.getpolnos
sd.scantable.get_fluxunit     sd.scantable.get_unit             sd.scantable.getscan
sd.scantable.get_parangle     sd.scantable.getbeam              sd.scantable.getscannos
```

These include functions to get the current values of the states mentioned above, as well as as methods to query the number of scans, IFs, and polarizations in the scantable, and their designations. See the inline help for the individual functions for more information.

### A.3.3.3 Masks

Several functions (fitting, baseline subtraction, statistics, etc) may be run on a range of channels (or velocity/frequency ranges). You can create masks of this type using the `create_mask` function:

```python
# spave = an averaged spectrum
spave.set_unit('channel')
rmsmask=spave.create_mask([5000,7000])  # create a region over channels 5000-7000
rms=spave.stats(stat='rms',mask=rmsmask)  # get rms of line free region

rmsmask=spave.create_mask([3000,4000],invert=True)  # choose the region
            # *excluding* the specified channels
```

The mask is stored in a simple Python variable (a list) and so may be manipulated using an Python facilities.
A.3.3.4 Scantable Management

scantables can be listed via:

CASA <33>: sd.list_scans()

The user created scantables are:
['scans20to24', 's', 'scan27']

As every scantable will consume memory, if you will not use it any longer, you can explicitly remove it via:

del <scantable name>

A.3.3.5 Scantable Mathematics

It is possible to do simple mathematics directly on scantables from the CASA command line using the +, −, *, / operators as well as their cousins +=, −=, *=, /=

CASA <10>: scan2=scan1+2.0 # add 2.0 to data
CASA <11>: scan *= 1.05 # scale spectrum by 1.05

NOTE: mathematics between two scantables is not currently available in ASAP.

A.3.3.6 Scantable Save and Export

ASAP can save scantables in a variety of formats, suitable for reading into other packages. The formats are:

- ASAP – This is the internal format used for ASAP. It is the only format that allows the user to restore the data, fits, etc, without loosing any information. As mentioned before, the ASAP scantable is a CASA Table (memory-based table). This function just converts it to a disk-based table. You can access this with the CASA browsetable task or any other CASA table tasks.

- SDFITS – The Single Dish FITS format. This format was designed for interchange between packages but few packages can actually read it.

- ASCII – A simple text based format suitable for the user to process using Python or other means.

- Measurement Set (V2: CASA format) – Saves the data in a Measurement Set. All CASA tasks which use an MS should work on this.

scans.save('output_filename','format'), e.g.,
CASA <19>: scans.save('FLS3a_calfs','MS2')
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

A.3.4 Calibration

For some observatories, the calibration happens transparently as the input data contains the Tsys measurements taken during the observations. The nominal ’Tsys’ values may be in Kelvin or Jansky. The user may wish to apply a Tsys correction or apply gain-elevation and opacity corrections.

A.3.4.1 Tsys scaling

If the nominal Tsys measurement at the telescope is wrong due to incorrect calibration, the scale function allows it to be corrected.

```
scans.scale(1.05, tsys=True)  # by default only the spectra are scaled
# (and not the corresponding Tsys) unless tsys=True
```

A.3.4.2 Flux and Temperature Unit Conversion

To convert measurements in Kelvin to Jansky (and vice versa), the convert_flux function may be used. This converts and scales the data to the selected units. The user may need to supply the aperture efficiency, telescope diameter or the Jy/K factor

```
scans.convert_flux(eta=0.48, d=35.)  # Unknown telescope
scans.convert_flux(jypk=15)  # Unknown telescope (alternative)
scans.convert_flux()  # known telescope (mostly AT telescopes)
scans.convert_flux(eta=0.48)  # if telescope diameter known
```

A.3.4.3 Gain-Elevation and Atmospheric Optical Depth Corrections

At higher frequencies, it is important to make corrections for atmospheric opacity and gain-elevation effects. **NOTE:** Currently, the MS to scantable conversion does not adequately populate the azimuth and elevation in the scantable. As a result, one must calculate these via:

```
scans.recalc_azel()
Computed azimuth/elevation using
Position: [882590, -4.92487e+06, 3.94373e+06]
  Time: 01:48:38 Direction: 05:35:13.5 -05.24.08.2
  => azel: 154.696 43.1847 (deg)
Time: 01:48:38 Direction: 05:35:13.5 -05.24.08.2
  => azel: 154.696 43.1847 (deg)
Time: 01:48:38 Direction: 05:35:13.5 -05.24.08.2
  => azel: 154.696 43.1847 (deg)
Time: 01:48:38 Direction: 05:35:13.5 -05.24.08.2
  => azel: 154.696 43.1847 (deg)
Time: 01:48:38 Direction: 05:35:13.5 -05.24.08.2
  => azel: 154.696 43.1847 (deg)
...```
Once you have the correct Az/El, you can correct for a known opacity by:

```python
scans.opacity(tau=0.09)  # Opacity from which the correction factor:
# exp(tau*zenith-distance)
```

### A.3.4.4 Calibration of GBT data

Data from the GBT is uncalibrated and comes as sets of integrations representing the different phases within a calibration cycle (e.g., on source, calibration on, on source, calibration off, on reference, calibration on; on reference, calibration off). Currently, there are a number of routines emulating the standard GBT calibration (in GBTIDL):

- `calps` - calibrate position switched data
- `calfs` - calibrate frequency switched data
- `calnod` - calibration nod (beam switch) data

All these routines calibrate the spectral data to antenna temperature adopting the GBT calibration method as described in the GBTIDL calibration document available at:

```none
```

There are two basic steps:

**First:** determine system temperature using a noise tube calibrator (sd.dototalpower())

For each integration, the system temperature is calculated from CAL noise on/off data as:

\[
T_{sys} = T_{cal} \times \frac{<r_{caloff}>_{refcalon}}{<r_{caloff}>_{refcalon} - refcaloff} + \frac{T_{cal}}{2}
\]

*ref* refers to reference data and the spectral data are averaged across the bandpass. Note that the central 80% of the spectra are used for the calculation.

**Second,** determine antenna temperature (sd.dosigref())

The antenna temperature for each channel is calculated as:

\[
T_a(\nu) = T_{sys} \times \frac{sig(\nu) - ref(\nu)}{ref(\nu)}
\]

where \(sig = \frac{1}{2}(sig_{calon} + sig_{caloff})\), \(ref = \frac{1}{2}(sig_{calon} + sig_{caloff})\).

Each calibration routine may be used as:

```python
scans=sd.scantable('inputdata',False)  # create a scantable called 'scans'
calibrated_scans = sd.calps(scans,[scanlist])  # calibrate scantable with position-switched
# scheme
```

**Note:** For calps and calnod, the scanlist must be scan pairs in correct order as these routines only do minimal checking.
A.3.5 Averaging

One can average polarizations in a scantable using the `sd.scantable.average_pol` function:

```
averaged_scan = scans.average_pol(mask, weight)
```

where:

- **Parameters:**
  - `mask`: An optional mask defining the region, where the averaging will be applied. The output will have all specified points masked.
  - `weight`: Weighting scheme. 'none' (default), 'var' (1/var(spec) weighted), or 'tsys' (1/Tsys**2 weighted)

**Example:**

```
spave = stave.average_pol(weight='tsys')
```

One can also average scans over time using `sd.average_time`:

```
sd.average_time(scantable, mask, scanav, weight, align)
```

where:

- **Parameters:**
  - `one scan or comma separated scans`
  - `compel`: if True, enable averaging of multi-resolution spectra.
  - `mask`: an optional mask (only used for 'var' and 'tsys' weighting)
  - `scanav`: True averages each scan separately. False (default) averages all scans together,
  - `weight`: Weighting scheme.
    - 'none' (mean no weight)
    - 'var' (1/var(spec) weighted)
    - 'tsys' (1/Tsys**2 weighted)
    - 'tint' (integration time weighted)
    - 'tintsys' (Tint/Tsys**2)
    - 'median' (median averaging)
  - `align`: align the spectra in velocity before averaging. It takes the time of the first spectrum in the first scantable as reference time.

**Example:**

```
stave = sd.average_time(scans, weight='tintsys')
```

Note that alignment of the velocity frame should be done before averaging if the time spanned by the scantable is long enough. This is done through the `align=True` option in `sd.average_time`, or explicitly through the `sd.scantable.freq_align` function, e.g.

```
CASA <62>: sc = sd.scantable('orions_scan20to23_if0to3.asap',False)
```
APPENDIX A. APPENDIX: SINGLE DISH DATA PROCESSING

CASA <63>: sc.freq_align()
Aligned at reference Epoch 2006/01/19/01:49:23 (UTC) in frame LSRK
CASA <64>: av = sd.average_times(sc)

The time averaging can also be applied to multiple scantables. This might have been taken on different days, for example. The sd.average_time function takes multiple scantables as input. However, if taken at significantly different times (different days for example) then sd.scantable.freq_align must be used to align the velocity scales to the same time, e.g.

CASA <65>: sc1 = sd.scantable('orions_scan21_if0to3.asap',False)
CASA <66>: sc2 = sd.scantable('orions_scan23_if0to3.asap',False)
CASA <67>: sc1.freq_align()
CASA <68>: sc2.freq_align(reftime='2006/01/19/01:49:23')
CASA <69>: scav = sd.average_times(sc1,sc2)

A.3.6 Spectral Smoothing

Smoothing on data can be done as follows:

scantable.smooth(kernel, # type of smoothing: 'hanning' (default), 'gaussian', 'boxcar'
    width, # width in pixls (ignored for hanning); FWHM for gaussian.
    insitu) # if False (default), do smoothing in-situ; otherwise,
            # make new scantable

Example:
# spave is an averaged spectrum
spave.smooth('boxcar',5) # do a 5 pixel boxcar smooth on the spectrum
sd.plotter.plot(spave) # should see smoothed spectrum

A.3.7 Baseline Fitting

The function sd.scantable.poly_baseline carries out a baseline fit, given an mask of channels (if desired):

msk=scans.create_mask([[100,400],[600,900]])
scans.poly_baseline(msk,order=1)

This will fit a first order polynomial to the selected channels and subtract this polynomial from the full spectrum.

The auto_poly_baseline function can be used to automatically baseline your data without having to specify channel ranges for the line free data. It automatically figures out the line-free emission and fits a polynomial baseline to that data. The user can use masks to fix the range of channels or velocity range for the fit as well as mark the band edge as invalid:
scans.auto_poly_baseline(mask, edge, order, threshold, chan_avg_limit, plot, insitu):

Parameters:
mask: an optional mask retrieved from scantable
edge: an optional number of channel to drop at
the edge of spectrum. If only one value is
specified, the same number will be dropped from
both sides of the spectrum. Default is to keep
all channels. Nested tuples represent individual
edge selection for different IFs (a number of spectral
channels can be different)
order: the order of the polynomial (default is 0)
threshold: the threshold used by line finder. It is better to
keep it large as only strong lines affect the
baseline solution.
chan_avg_limit:
a maximum number of consecutive spectral channels to
average during the search of weak and broad lines.
The default is no averaging (and no search for weak
lines). If such lines can affect the fitted baseline
(e.g. a high order polynomial is fitted), increase this
parameter (usually values up to 8 are reasonable). Most
users of this method should find the default value
sufficient.
plot: plot the fit and the residual. In this each
individual fit has to be approved, by typing 'y'
or 'n'
isitu: if False a new scantable is returned.
Otherwise, the scaling is done in-situ
The default is taken from .asaprc (False)

Example:
screens.auto_poly_baseline(order=2, threshold=5)

A.3.8 Line Fitting

Multi-component Gaussian fitting is available. This is done by creating a fitting object, specifying
fit parameters and finally fitting the data. Fitting can be done on a scantable selection or an
entire scantable using the auto_fit function.

#spave is an averaged spectrum
f=sd.fitter() # create fitter object
msk=spave.create_mask([3928,4255]) # create mask region around line
f.set_function(gauss=1) # set a single gaussian component
f.set_scan(spave, msk) # set the scantable and region
#
# Automatically guess start values
f.fit() # fit
f.plot(residual=True) # plot residual
f.get_parameters()  # retrieve fit parameters
# 0: peak = 0.786 K , centre = 4091.236 channel, FWHM = 70.586 channel
# area = 59.473 K channel
f.store_fit('orions_hc3n_fit.txt')  # store fit
#
# To specify initial guess:
f.set_function(gauss=1)  # set a single gaussian component
f.set_gauss_parameters(0.4,4100,200, component=0)  # set initial guesses for Gaussian
# for first component (0)
# (peak,center,fwhm)
#
# For multiple components set
# initial guesses for each, e.g.
f.set_function(gauss=2)  # set two gaussian components
f.set_gauss_parameters(0.4,4100,200, component=0)  # set initial guesses for Gaussian
# for first component (0)
f.set_gauss_parameters(0.1,4200,100, component=1)  # set initial guesses for Gaussian
# for second component (1)

A.3.9 Plotting

A.3.9.1 ASAP plotter

The ASAP plotter uses the same Python matplotlib library as in CASA (for x-y plots). It is accessed via the:

sd.plotter  # see all functions (omitted here)
sd.plotter.plot(scans)  # the workhorse function
sd.plotter.set<TAB>
sd.plotter.set_abcissa sd.plotter.set_legendsd.plotter.set_range
sd.plotter.set_colors sd.plotter.set_linestyles sd.plotter.set_selection
sd.plotter.set_colours sd.plotter.set_mask sd.plotter.set_stacking
sd.plotter.set_font sd.plotter.set_mode sd.plotter.set_title
sd.plotter.set_histogram sd.plotter.set_ordinate
sd.plotter.set_layout sd.plotter.set_panelling

Spectra can be plotted at any time, and it will attempt to do the correct layout depending on whether it is a set of scans or a single scan.

The details of the plotter display (matplotlib) are detailed in the earlier section.

A.3.9.2 Line Catalog

ASAP allows to load a custom line catalog in ASCII format. The ASCII text file must have at least 4 columns with Molecule name, frequency in MHz, frequency error and intensity (any units). If the molecule name contains any spaces, they must be wrapped in quotes "". A sample of the ASCII catalog is shown below.
H2D+ 3955.2551 228.8818 -7.1941
H2D+ 12104.7712 177.1558 -6.0769
H2D+ 45809.2731 118.3223 -3.9494
CH 701.6811 .0441 -7.1641
CH 724.7709 .0456 -7.3912
CH 3263.7940 .1000 -6.3501
CH 3335.4810 .1000 -6.0304

You can load the ASCII line catalog, for example, if it is called my_custom_linecat.txt, by following command.

```
mycatalog = sd.linecatlog('my_custom_linecat.txt')
```

Use `sd.plotter.plot_line` to overlay the line catalog on the plot. (Currently overplotting line catalog works only spectra plotted in frequency.)

```
scans.set_unit('GHz')
sd.plotter.plot(scans)
sd.plotter.plot_line(mycatalog)
```

Following are some useful functions to control the line catalog access. See ASAP User Guide for more complete descriptions.

```
mycatalog.save('my_custom_linecat.tbl') # save to the internal table format
mycatalog.set_frequency_limits(100,115,'GHz') #set a frequency range for line selection
mycatalog.set_name('*OH') # select all alcohols
```

### A.3.10 Setting/Getting Rest Frequencies

The rest frequencies used in the data can be retrieve by `sd.scantable.get_restfreqs()` and set to new values by `sd.scantable.set_restfreqs()`. The CASA version of ASAP now can store multiple rest frequencies for each IF.

```
scans.get_restfreqs() #retrieve current rest frequencies
#{0: [45490258000.0]
```

All the rest frequencies currently set to the data are listed in python dictionary for each MOLECULE_ID.

To set multiple rest frequencies to spectra for a particular IF, for example,

```
#Select IFs, then set rest frequencies,
sel=sd.selector()
sel.setifs(0)
scans.set_selection(sel)
scans.set_restfreqs([45490258000.0,45590258000.0,45690258000.0])
```

NOTE: there is no functionality yet to select a specific rest frequency to apply to a specific line, etc. Currently, the first one in the list of the rest frequencies is used for such calculation.
A.3.11 Single Dish Spectral Analysis Use Case With ASAP Toolkit

Below is a script that illustrates how to reduce single dish data using ASAP within CASA. First a summary of the dataset is given and then the script.

```python
# MeasurementSet Name: /home/rohir3/jocular/SD/OrionS_rawACSmod MS Version 2
# Project: AGBT06A_018_01
# Observation: GBT(1 antennas)

#
# Scans: 21-24 Setup 1 HC3N et al
# Scans: 25-28 Setup 2 SiO et al

casapath=os.environ['AIPSPATH']

#ASAP script
#-------------------------------------- -----------------------------------------------
import asap as sd  #import ASAP package into CASA
#Orion-S (SiO line reduction only)
#Notes:
#scan numbers (zero-based) as compared to GBTIDL
#changes made to get to OrionS_rawACSmod
#modifications to label sig/ref positions
os.environ['AIPSPATH']=casapath  #set this environment variable back - ASAP changes it

s=sd.scantable('OrionS_rawACSmod',False)#load the data without averaging
```
Figure A.3: Multi-panel display of the scantable. There are two plots per scan indicating the _psr (reference position data) and the _p (source data).

```
s.summary()  # summary info
s.set_fluxunit('K')  # make 'K' default unit
scal=sd.calps(s,[20,21,22,23])  # Calibrate HC3N scans
scal.recalc_azel()  # recalculate az/el to
scal.opacity(0.09)  # do opacity correction
sel=sd.selector()  # Prepare a selection
sel.set_ifs(0)  # select HC3N IF
scal.set_selection(sel)  # get this IF
stave=sd.average_time(scal,weight='tintsys')  # average in time
spave=stave.average_pol(weight='tsys')  # average polarizations; Tsys-weighted (1/Tsys**2) average
sd.plotter.plot(spave)  # plot
spave.smooth('boxcar',5)  # boxcar 5
spave.auto_poly_baseline(order=2)  # baseline fit order=2
sd.plotter.plot(spave)  # plot
spave.set_unit('GHz')
```

```
sd.plotter.set_histogram(hist=True)  # draw spectrum using histogram
sd.plotter.axhline(color='r',linewidth=2)  # zline
sd.plotter.save('orions_hc3n_reduced.eps')  # save postscript spectrum
```
Figure A.4: Two panel plot of the calibrated spectra. The GBT data has a separate scan for the SOURCE and REFERENCE positions so scans 20, 21, 22 and 23 result in these two spectra.

Figure A.5: Calibrated spectrum with a line at zero (using histograms).
spave.set_unit('channel')
rmsmask=spave.create_mask([5000,7000])  # get rms of line free regions
rms=spave.stats(stat='rms',mask=rmsmask)  # rms
# Scan[0] (OrionS_ps) Time[2006/01/19/01:52:05]:
# IF[0] = 0.048
# LINE
linemask=spave.create_mask([3900,4200])
max=spave.stats('max',linemask)  # IF[0] = 0.918
sum=spave.stats('sum',linemask)  # IF[0] = 64.994
median=spave.stats('median',linemask)  # IF[0] = 0.091
mean=spave.stats('mean',linemask)  # IF[0] = 0.210

spave.set_unit('channel')  # set units to channel
sd.plotter.plot(spave)  # plot spectrum
f=sd.fitter()
msk=spave.create_mask([3928,4255])  # create region around line
f.set_function(gauss=1)  # set a single gaussian component
f.set_scan(spave,msk)  # set the data and region for the fitter
f.fit()  # fit
f.plot(residual=True)  # plot residual
f.get_parameters()  # retrieve fit parameters
# 0: peak = 0.786 K , centre = 4091.236 channel, FWHM = 70.586 channel
# area = 59.473 K channel
f.store_fit('orions_hc3n_fit.txt')  # store fit
# Save the spectrum
spave.save('orions_hc3n_reduced','ASCII',True)  # save the spectrum

A.4 Single Dish Imaging

Single dish imaging is supported within CASA using standard tasks and tools. The data must be in the Measurement Set format. Once there, you can use the `im (imager)` tool to create images:

Tool example:

```python
scans.save('outputms','MS2')  # Save your data from ASAP into an MS
im.open('outputms')  # open the data set
im.selectvis(nchan=901,start=30,step=1, spwid=0,field=0)
dir='J2000 17:18:29 +59.31.23'
im.defineimage(nx=150,cellx='1.5arcmin',)
```
A.4.1 Single Dish Imaging Use Case With ASAP Toolkit

Again, the data summary and then the script is given below.

```
# Project: AGBT02A_007_01
# Observation: GBT(1 antennas)
#

nchan=901,step=1) # aren't specified)
im.setoptions(ftmachine='sd',cache=1000000000) # choose SD gridding
im.setsdoptions(convsupport=4) # use this many pixels to support the
# gridding function used
# (default=prolate spheroidal wave function)
im.makeimage(type='singledish',image='FLS3a_HI.image') # make the image
Figure A.6: FLS3a HI emission. The display illustrates the visualization of the data cube (left) and the profile display of the cube at the cursor location (right); the Tools menu of the Viewer Display Panel has a Spectral Profile button which brings up this display. By default, it grabs the left-mouse button. Pressing down the button and moving in the display will show the profile variations.

A.5 Known Issues, Problems, Deficiencies and Features

The Single-Dish calibration and analysis package within CASA is still very much under development. Not surprisingly, there are a number of issues with ASAP and the SDtasks that are known and are under repair. Some of these are non-obvious "features" of the way ASAP or sd is implemented, or limitations of the current Python tasking environment. Some are functions that have yet to be implemented. These currently include:

1. sd.plotter

Currently you can get hardcopy only after making a viewed plot. Ideally, ASAP should allow you to choose the device for plotting when you set up the plotter.

Multi-panel plotting is poor. Currently you can only add things (like lines, text, etc.) to the first panel. Also, sd.plotter.set_range() sets the same range for multiple panels, while we would like it to be able to set the range for each independently, including the default ranges.

The appearance of the plots need to be made a lot better. In principle matplotlib can make "publication quality" figures, but in practice you have to do a lot of work to make it do that, and our plots are not good.

The sd.plotter object remembers things throughout the session and thus can easily get confused. For example you have to reset the range sd.plotter.set_range() if you have ever
set it manually. This is not always the expected behavior but is a consequence of having `sd.plotter` be its own object that you feed data and commands to.

There are known bugs if you try to switch between the task-based plotting with `sdplot` and the tool-based plotting. the `sdplot` adds extra control buttons and this is not implemented in the sd toolkit so no 'spec value','statistics', nor 'Quit' button for the plotter display with `sd.plotter.plot()`. Once 'statistics' button on `sdplot` is used and deleted `sdplot` display with 'Quit' button, you can still use mouse buttons to select region to get statistics with the plotter displayed with `sd.plotter.plot()`. But spectral values won't be displayed in such case. Also, if you try to go back `sdplot` after using `sd.plotter.plot()`, you may encounter an error and the plotter window won't be displayed. In that case, you can reset the window state by deleting the plotter window opened by `sd.plotter.plot()`, with the command, `sd.plotter._plotter.unmap()`.

Eventually we would like the capability to interactively set things using the plots, like select frequency ranges, identify lines, start fitting.

2. `sd.selector`

   The selector object only allows one selection of each type. It would be nice to be able to make a union of selections (without resorting to query) for the `set.name` - note that the others like scans and IFs work off lists which is fine. Should make `set.name` work off lists of names.

3. `sd.scantable`

   There is no useful inline help on the scantable constructor when you do `help sd.scantable`, nor in help sd.

   The inline help for scantable.summary claims that there is a verbose parameter, but there is not. The scantable.verbosesummary asaprc parameter (e.g. in `sd.rcParams`) does nothing.

   GBT data has undefined fluxunit ('', should be 'K'), incorrect freqframe ('LSRK', is really 'TOPO') and reference frequency (set to that of the first IF only).

   The `sd.scantable.freq.align` does not yet work correctly.

4. `sd` general issues

   There should be a `sdhelp` equivalent of `toolhelp` and `tasklist` for the sd tools and tasks.

   The current output of ASAP is verbose, and is controlled by setting `sd.rcParams['verbose']`=False (or True). At the least we should make some of the output less cryptic.

   Strip off leading and trailing whitespace on string parameters.

5. SDtasks general issues

   The SDtasks work off of files saved onto disk in one of the scantable supported formats. It might be useful to be able to work off of scantables in memory (passing the objects) but this would require changes to the tasking system. Note that this behavior is consistent throughout the casapy tasks.

6. `sdaverage` (and `sdcal`)

   `averageall=True` is still experimental since test was insufficient because of a lack of test data.
7. **sdfit**
   
   Only way to handle multi-IFs is to set fitmode='auto'. (linefinder is applied for each spectra and derives initial guesses) For fitmode='list', there are no way to give initial guesses for each IFs by hand.

8. **sdplot**
   
   Only handles included JPL line catalog.
   
   Also, see **sd.plotter** issues above.
Appendix B

Simulation

**BETA ALERT:** The simulation capabilities are currently under development. What we do have is mostly at the Toolkit level. We have only a single task `almasimmos` at the present time. Stay tuned. For the Beta Release, we include this chapter in the Appendix for the use of telescope commissioners and software developers.

The capability for simulating observations and datasets from the EVLA and ALMA are an important use-case for CASA. This not only allows one to get an idea of the capabilities of these instruments for doing science, but also provides benchmarks for the performance and utility of the software for processing “realistic” datasets. To that end, we are developing the simulator (sm) tool, as well as a series of simulation tasks.

**B.1 Simulating ALMA with almasimmos**

**BETA ALERT:** This is an experimental task that is under development. Its functionality and parameters will be changing, so check the on-line documentation for the latest updates.

The inputs are:

```plaintext
# almasimmos :: ALMA Mosaic simulation task

Please see the on-line documentation for this task.

project = 'mysim' # name of simulated project
modelimage = '' # image name to derive simulate visibilities
complist = '' # componentlist table to derive simulated visibilities
antennalist = '' # antenna position ascii file
direction = 'J2000 19h00m00 -40d00m00' # mosaic center direction
nmosx = 1 # number of pointings along x
```

---

**Inside the Toolkit:**
The simulator methods are in the sm tool. Many of the other tools are also helpful when constructing and analyzing simulations.
APPENDIX B. APPENDIX: SIMULATION

nmosy = 1  # number of pointings along y
pointingspacing = '5arcmin'  # spacing in between beams
refdate = '2012/05/21/22:05:00'  # center time/date of simulated observation
totaltime = '7200s'  # total time of observation
integration = '10s'  # integration (sampling) time
mode = 'channel'  # type of selection: channel, continuum
alg = 'clark'  # deconvolution algorithm: clark, hogbom, multiscale
niter = 500  # number iterations
nchan = 1  # number of channels to select
startfreq = '89GHz'  # frequency of first channel
chanwidth = '10MHz'  # channel width
imsize = [250, 250]  # Image pixel size (x,y)
cell = '10arcsec'  # Cell size e.g., 10arcsec
stokes = 'I'  # Stokes parameters to image
weighting = 'natural'  # Weighting of visibilities
display = True  # Plot simulation result images, figures

This task takes an input model image or list of components, plus a list of antennas (locations and sizes), and simulates a particular observation (specifies by mosaic setup and observing cycles and times). This is currently very simplistic. For example, it does not include noise by default, or gain errors (but see the on-line wiki documentation for how to do these). The output is a MS suitable for further processing in CASA.

Its name implies that it is for ALMA, but it is mostly general as you can give it any antenna setup — it does have the ALMA observatory location hardwired in and sets the telescope name to 'ALMA' but that's about it. The task could be easily modified for other instruments.

**BETA ALERT:** Because of the experimental nature of this task, we do not provide extensive documentation in this cookbook. For this purpose, there is an on-line "wiki" devoted to this task:

[https://wikio.nrao.edu/bin/view/ALMA/SimulatorCookbook](https://wikio.nrao.edu/bin/view/ALMA/SimulatorCookbook)

Here you can find what documentation we do have, along with example files that are needed to specify antenna locations, and a FAQ.
Appendix C

Obtaining and Installing CASA

C.1 Installation Script

Currently you must be able to log into your system as the root user or an administrator user to install CASA.

The easiest way to install CASA on a RedHat Enterprise Linux (or compatible) system is to use our installation script, load-casapy. This script will ftp the CASA RPMs and install them. To use it, first use the link above to download it to your hard disk. Next, make sure execute permission is set for the file.

Install CASA into /usr by logging in as root and running:

load-casapy –root

This option will install CASA into /usr, but it can only be run by the root user.

Alternatively, you can visit our FTP server, download the rpms, and install them by hand. Note: you must be root/administrator to install CASA in this manner.

See the following for more details:
https://wikio.nrao.edu/bin/view/Software/ObtainingCASA

C.2 Startup

This section assumes that CASA has been installed on your LINUX or OSX system. For NRAO-AOC testers, you should do the following on an AOC RHE4 machine:

> ./home/casa/casainit.sh
or
> source /home/casa/casainit.csh
Appendix D

Python and CASA

CASA uses Python, IPython and matplotlib within the package. IPython is an enhanced, interactive shell to Python which provides many features for efficient command line interaction, while matplotlib is a Python 2-D plotting library for publication quality figures in different hardcopy formats.

From www.python.org: "Python is an interpreted, interactive, object-oriented programming language". Python is used as the underlying command line interface/scripting language to CASA. Thus, CASA inherits the features and the annoyances of Python. For example, since Python is inherently 0-based in its indexing of arrays, vectors, etc, CASA is also 0-based; any Index inputs (e.g., start (for start channel), fieldIndex, antennaID, etc) will start with 0. Another example is that indenting of lines means something to Python, of which users will have to be aware.

Some key links are:

- [http://python.org](http://python.org) – Main Python page
- [http://python.org/doc/2.4.2/ref/ref.html](http://python.org/doc/2.4.2/ref/ref.html) – Python Reference
- [http://python.org/doc/2.4.2/tut/tut.html](http://python.org/doc/2.4.2/tut/tut.html) – Python Tutorial
- [http://ipython.scipy.org](http://ipython.scipy.org) – IPython page

Each of the features of these components behave in the standard way within CASA. In the following sections, we outline the key elements for analysis interactions; see the Python references and the IPython page for the full suite of functionality.

D.1 Automatic parentheses

Automatic parenthesis is enabled for calling functions with argument lists; this feature is intended to allow less typing for common situations. IPython will display the interpretation of the line,
beneath the one typed, as indicated by the ‘--------’ . Default behavior in CASA is to have automatic parenthesis enabled.

### D.2 Indentation

Python pays attention to indentation of lines in scripts or when you enter them interactively. It uses indentation to determine the level of nesting in loops. Be careful when cutting and pasting, if you get the wrong indentation, then unpredictable things can happen (usually it just gives an error).

A blank line can be used to return the indentation to a previous level. For example, expanded parameters in tasks cause indentation in subsequent lines in the interface. For example, the following snippet of inputs from `clean` can be cut and pasted without error due to the blank line after the indented parameters:

```python
mode = 'channel'  # Type of selection
nchan = -1        # Number of channels to select
start = 0         # Start channel
step = 1          # Increment between channels/velocity
width = 1         # Channel width
alg = 'clark'     # Algorithm to use
```

If the blank line were not there, an error would result if you pasted this at the `casapy` prompt.

### D.3 Lists and Ranges

Sometimes, you need to give a task a list of indices. For example, some tasks and tools expect a comma-separated Python list, e.g.

```python
scanlist = [241, 242, 243, 244, 245, 246]
```

You can use the Python `range` function to generate a list of consecutive numbers, e.g.

```python
scanlist = range(241,247)
```

giving the same list as above, e.g.

CASA <1>: scanlist=range(241,247)
CASA <2>: print scanlist
[241, 242, 243, 244, 245, 246]

Note that `range` starts from the first limit and goes to one below the second limit (Python is 0-based, and `range` is designed to work in loop functions). If only a single limit is given, the first limit is treated as 0, and the one given is used as the second, e.g.
D.4 Dictionaries

Python dictionaries are data structures that contain key:value pairs, sort of like a hash array. These are useful to store mini-databases of things. In CASA, the parameter values are kept in a dictionary behind the scenes.

To initialize a dictionary, say we call it mydict, for use:

CASA <7>: mydict = {}

To add members:

CASA <8>: mydict['source'] = '0137+331'
CASA <9>: mydict['flux'] = 5.4

To see its contents:

CASA <10>: mydict
   Out[10]: {'flux': 5.4000000000000004, 'source': '0137+331'}
CASA <11>: print mydict
   {'source': '0137+331', 'flux': 5.4000000000000004}

To access a specific entry:

CASA <12>: print mydict['flux']
   5.4

D.4.1 Saving and Reading Dictionaries

To save a simple dictionary to a file:

CASA <13>: dictfile = open('mydictfile.py','w')
CASA <14>: print >>dictfile,"mydict = ",mydict
CASA <15>: dictfile.close()
CASA <16>: !cat mydictfile.py
IPython system call: cat mydictfile.py
mydict = {'source': '0137+331', 'flux': 5.4000000000000004}

CASA <17>: mydict = {}
CASA <18>: run mydictfile.py
CASA <19>: mydict
Out[19]: {'flux': 5.4000000000000004, 'source': '0137+331'}

More complex dictionaries, like those produced by `imstat` that contain NumPy arrays, require a different approach to save. The `pickle` module lets you save general data structures from Python. For example:

CASA <20>: import pickle
CASA <21>: xstat
Out[21]:
{'blc': array([0, 0, 0, 0]),
'blcf': '15:24:08.404, +04.31.59.181, I, 1.41281e+09Hz',
'flux': array([ 4.0795296]),
'max': array([ 0.05235516]),
'maxpos': array([134, 134, 0, 38]),
'maxposf': '15:21:53.976, +05.05.29.998, I, 1.41374e+09Hz',
'mean': array([ 1.6097857e-05]),
'medabsdevmed': array([ 0.00127436]),
'median': array([-1.17422514e-05]),
'min': array([-0.0104834]),
'minpos': array([160, 1, 0, 30]),
'minposf': '15:21:27.899, +04.32.14.923, I, 1.41354e+09Hz',
'npts': array([ 3014656.]),
'quartile': array([ 0.00254881]),
'rms': array([ 0.00202226]),
'sigma': array([ 0.00202222]),
'sum': array([ 48.26399646]),
'sumsq': array([ 12.32857318]),
'trc': array([255, 255, 0, 45]),
'trcf': '15:19:52.390, +05.35.44.246, I, 1.41391e+09Hz'}

CASA <22>: mydict
Out[22]: {'flux': 5.4000000000000004, 'source': '0137+331'}

CASA <23>: pickfile = 'myxstat.pickle'
CASA <24>: f = open(pickfile,'w')
CASA <25>: p = pickle.Pickler(f)
CASA <26>: p.dump(xstat)
CASA <27>: p.dump(mydict)
CASA <28>: f.close()

The dictionaries are now saved in `pickle` file `myxstat.pickle` in the current directory.

To retrieve:

CASA <29>: xstat2 = {}/
APPENDIX D. APPENDIX: PYTHON AND CASA

Thus, you can make scripts that save information and use it later, like for regressions.

Note that these examples use Python file-handling and IO, as well as importing modules such as pickle. See your friendly Python reference for more on this kind of stuff. Its fairly obvious how it works.

D.5 Control Flow: Conditionals, Loops, and Exceptions

There are a number of ways to control the flow of execution in Python, including conditionals (if), loops (for and while), and exceptions (try). We will discuss the first two below.

D.5.1 Conditionals

The standard if block handles conditional execution or branches in Python:
if <expression>:
    <statements>
elif <expression>:
    <statements>
elif <expression>:
    <statements>
...
else:
    <statements>

Insert a `pass` statement if you want no action to be taken for a particular clause. The `<expression>` should reduce down to `True` or `False`.

For example,

```python
if ( importmode == 'vla' ):
    # Import the data from VLA Export to MS
    default('importvla')
    print "Use importvla to read VLA Export and make an MS"
    archivefiles = datafile
    vis = msfile
    bandname = exportband
    autocorr = False
    antnamescheme = 'new'
    project = exportproject
    importvla()
elif ( importmode == 'fits' ):
    # Import the data from VLA Export to MS
    default('importuvfits')
    print "Use importuvfits to read UVFITS and make an MS"
    fitsfile = datafile
    vis = msfile
    async = False
    importuvfits()
else:
    # Copy from msfile
    print "Copying "+datafile+" to "+msfile
    os.system('cp -r '+datafile+ ' '+msfile)
    vis = msfile
```

chooses branches based on the value of the `importmode` Python variable (set previously in script).
D.5.2 Loops

The for loop

    for iter in seq:
        <statements>

iterates over elements of a sequence seq, assigning each in turn to iter. The sequence is usually a list of values.

For example,

```python
splitms = 'polcal_20080224.cband.all.split.ms'
srclist = ['0137+331','2136+006','2202+422','2253+161','0319+415','0359+509']
spwlist = ['0','1']

for src in srclist:
    for spwid in spwlist:
        imname = splitms + '.' + src + '.' + spwid + '.clean'
        clean(vis=splitms,field=src,spw=spwid,imagename=imname,
              stokes='IQUV',psfmode='hogbom',imagermode='csclean',
              imsize=[288,288],cell=[0.4,0.4],niter=1000,
              threshold=1.3,mask=[134,134,154,154])

# Done with spw
# Done with sources
```

As usual, blocks are closed by blank lines of the previous indentation level.

You can use the range (§D.3) Python function to generate a numerical loop:

```python
vis = 'polcal_20080224.cband.all.ms'
for i in range(0,6):
    fld = str(i)
    plotxy(vis,field=fld,xaxis='uvdist',yaxis='amp')

# Done with fields [0, 1, 2, 3, 4, 5]
```

There is also a while loop construct

    while <expression>:
        <statements>

which executes the statement block while the <expression> is True. The while loop can also take an else block.

For example,
# Do an explicit set of clean iterations down to a limit
prevrms = 1.e10
while rms > 0.001 :
    clean(vis=splitms,field=src,spw=spwid,imagename=imname,
          stokes='IQUV',psfmode='hogbom',imagermode='csclean',
          imsize=[288,288],cell=[0.4,0.4],niter=200,
          threshold=1.3,mask=[134,134,154,154])

    offstat=imstat(imname+'.residual',box='224,224,284,284')
    rms=offstat['sigma'][0]
    if rms > prevrms:
        break  # the rms has increased, stop

    prevrms = rms

# Clean until the off-source rms residual, reaches 0.001 Jy

Note that you can exit a loop using the `break` statement, as we have here when the rms increases.

## D.6 System shell access

For scripts, the `os.system` methods are the preferred way to access system shell commands (see §[D.6.1](#D.6.1)).

In interactive mode, any input line beginning with a `'!'` character is passed verbatim (minus the `'!'`) to the underlying operating system. Several common commands (`ls`, `pwd`, `less`) may be executed with or without the `'!'`. Note that the `cd` command must be executed without the `'!'`, and the `cp` command must use `'!'` as there is a conflict with the `cp` tool in `casapy`.

For example:

```
CASA [1]: pwd
/export/home/corsair-vml/jmcmulli/data
CASA [2]: ls n*
ngc5921.ms ngc5921.py
CASA [3]: !cp -r ../test.py .
```

### D.6.1 Using the `os.system` methods

To use this, you need the `os` package. This should be loaded by default by `casapy`, but if not you can use

```python
import os
```

in your script.

For example, in our scripts we use this to clean up any existing output files
# The prefix to use for all output files
prefix='ngc5921.usecase'

# Clean up old files
os.system('rm -rf '+prefix+'*')

Note that the os package has many useful methods. You can see these by using tab-completion:

CASA <2>: os.<tab>
Display all 223 possibilities? (y or n)
os.EX_CANTCREAT os.X_OK os.fdatasync os.readlink
os.EX_CONFIG os._Environ os.fdopen os.remove
os.EX_DATAERR os._all__ os.fork os.removedirs
os.EX_IOERR os._class__ os.forkpty os.rename
os.EX_NOHOST os._delattr__ os.fpathconf os.renames
os.EX_NOINPUT os._dict__ os.fstat os.rmdir
os.EX_NOPERM os._doc__ os.fstatvfs os.sep
os.EX_Nouser os._file__ os.fs蠢c os.setegid
os.EX_OK os._getAttribute__ os.ftruncate os.seteuid
os.EX_OSFILE os._init__ os.getcwdu os.setgid
os.EX_PROTOCOL os._name__ os.getegid os.setpgid
os.EX_SOFTWARE os._new__ os.getenv os.setpgpr
os.EX_TEMPFAIL os._reduce__ os.geteuid os.setregid
os.EX_UNAVAILABLE os._reduce_ex__ os.getgid os.setreuid
os.EX_USAGE os._repr__ os.setgroups os.setsiz
os.F_OK os._setattr__ os.getloadavg os.setuid
os.NGROUPS_MAX os._str__ os.getlogin os.spawnl
os.O_APPEND os._copy_re5 os.getpgid os.spawnle
os.O_CREAT os._execvpe os.getpgrp os.spawnlpe
os.O_DIRECT os._exists os.getpid os.spawnvp
os.O_DIRECTORY os._exit os.getppid os.spawnv
os.O_LARGEFILE os._get_exports_list os.getsid os.spawnvpe
os.O_EXCL os._make_stat_result os.getuid os.spawnvp
os.O_NDELAY os._make_statvfs_result os.isatty os.spawnvpe
os.O_NOCTTY os._pickle_stat_result os.kill os.stat
os.O_RDONLY os._pickle_statvfs_result os.killpg os.stat_float_times
os.O_NOFOLLOW os._spawnv os.lchown os.stat_result
os.O_NONBLOCK os.abort os.linesep os.statfs
os.O_RDONLY os.access os.link os.statvfs_result
os.O_RDONLY os.altsep os.listdir os.strerror
os.O_RDONLY os.chdir os.lseek os.sys
os.O_RDONLY os.chdir os.lseek os.sys
os.O_RDONLY os.chmod os.lstat os.sys
os.O_RDONLY os.chown os.major os.sysconf
os.O_RDONLY os.chroot os.makedev os.sysconf_names
os.O_RDONLY os.close os.makedirs os.system
os.O_RDONLY os.confstr os.major os.tcgetpgrp
os.P_WAIT os.confstr_names os.mkdir os.tcsetpgrp
os.P_WAIT os.confstr_names os.mknod os.temporary
os.P_WAIT os.defpath os.name os.tmpfile
os.P_WAIT os.defpath os.name os.tmpfile
D.6.2 Directory Navigation

In addition, filesystem navigation is aided through the use of bookmarks to simplify access to frequently-used directories:

```
CASA [4]: cd /home/ballista/jmcmulli/other_data
CASA [4]: pwd
/home/ballista/jmcmulli/other_data
CASA [5]: bookmark other_data
CASA [6]: cd /export/home/corsair-vml/jmcmulli/data
CASA [7]: pwd
/export/home/corsair-vml/jmcmulli/data
CASA [8]: cd -b other_data
(bookmark:data) -> /home/ballista/jmcmulli/other_data
```

D.6.3 Shell Command and Capture

See also §D.8 for the use of the command history.

1. sx shell_command, !!shell_command - this captures the output to a list

```
CASA [1]: sx pwd # stores output of 'pwd' in a list
  Out[1]: ['/home/basho3/jmcmulli/pretest']

CASA [2]: !!pwd # !! is a shortcut for 'sx'
  Out[2]: ['/home/basho3/jmcmulli/pretest']

CASA [3]: sx ls v* # stores output of 'pwd' in a list
  Out[3]:
    ['vla_calplot.jpg',
     'vla_calplot.png',
     'vla_msplot_cals.jpg',
    ]
```
'vla_msplot_cals.png',
'vla_plotcal_bpass.jpg',
'vla_plotcal_bpass.png',
'vla_plotcal_fcal.jpg',
'vla_plotcal_fcal.png',
'vla_plotvis.jpg',
'vla_plotvis.png']

CASA [4]: x=_ # remember '_' is a shortcut for the output from the last command

CASA [5]: x
Out[5]: ['vla_calplot.jpg',
        'vla_calplot.png',
        'vla_msplot_cals.jpg',
        'vla_msplot_cals.png',
        'vla_plotcal_bpass.jpg',
        'vla_plotcal_bpass.png', 'vla_plotcal_fcal.jpg',
        'vla_plotcal_fcal.png',
        'vla_plotvis.jpg',
        'vla_plotvis.png']

CASA [6]: y=Out[2] # or just refer to the enumerated output

CASA [7]: y
Out[7]: ['/home/basho3/jmcmulli/pretest']

2. sc - captures the output to a variable; options are '-l' and '-v'

CASA [1]: sc x=pwd # capture output from 'pwd' to the variable 'x'

CASA [2]: x
Out[2]: '/home/basho3/jmcmulli/pretest'

CASA [3]: sc -l x=pwd # capture the output from 'pwd' to the variable 'x' but
    # split newlines into a list (similar to sx command)

CASA [4]: x
Out[4]: ['/home/basho3/jmcmulli/pretest']

CASA [5]: sc -v x=pwd # capture output from 'pwd' to a variable 'x' and
    # show what you get (verbose mode)

x ==
'/home/basho3/jmcmulli/pretest'

CASA [6]: x
Out[6]: '/home/basho3/jmcmulli/pretest'
D.7 Logging

There are two components to logging within CASA. Logging of all command line inputs is done via IPython.

Upon startup, CASA will log all commands to a file called ipython.log. This file can be changed via the use of the ipythonrc file. This log file can be edited and re-executed as appropriate using the execfile feature (§D.11).

The following line sets up the logging for CASA. There are four options following the specification of the logging file: 1) append, 2) rotate (each session of CASA will create a new log file with a counter incrementing ipython.log.1, ipython.log.2 etc, 3) over (overwrite existing file), and 4) backup (renames existing log file to logname).

```
logfile ./ipython.log append
```

The command logstate will provide details on the current logging setup:

```
CASA [12]: logstate

File:     ipython.log
Mode:     append
State:    active
```

Logging can be turned on and off using the logon, logoff commands.

The second component is the output from applications which is directed to the file ./casapy.log. See §1.4.2 for more on the casalogger.

D.8 History and Searching

Numbered input/output history is provided natively within IPython. Command history is also maintained on-line.

```
CASA [11]: x=1
CASA [12]: y=3*x
CASA [13]: z=x**2+y**2
CASA [14]: x
   Out[14]: 1
CASA [15]: y
   Out[15]: 3
```
CASA [16]: z
   Out[16]: 10

CASA [17]: Out[14]  # Note: The 'Out' vector contains command output
   Out[17]: 1

CASA [18]: _15  # Note: The return value can be accessed by _number
   Out[18]: 3

CASA [19]: ___  # Note: The last three return values can be accessed as:
   Out[19]: 10  # _, __, ___

Command history can be accessed via the 'hist' command. The history is reset at the beginning of every CASA session, that is, typing 'hist' when you first start CASA will not provide any commands from the previous session. However, all of the commands are still available at the command line and can be accessed through the up or down arrow keys, and through searching.

CASA [22]: hist
1 : __IP.system("vi temp.py")  # Note:shell commands are designated in this way
2 : ipmagic("run -i temp.py")  # Note:magic commands are designated in this way
3 : ipmagic("hist ")
4 : more temp.py
5 : __IP.system("more temp.py")
6 : quickhelp()  # Note: autoparenthesis are added in the history
7 : im.open('ngc5921.ms')
8 : im.summary()
9 : ipmagic("pdoc im.setdata")
10: im.close()
11: quickhelp()
12: ipmagic("logstate ")
13: x=1
14: y=3*x
15: z=x**2+y**2
16: x
17: y
18: z
19: Out[16]
20: _17
21: ___

The history can be saved as a script or used as a macro for further use:

CASA [24]: save script.py 13:16
   File 'script.py' exists. Overwrite (y/[N])? y
   The following commands were written to file 'script.py':
     x=1
     y=3*x
     z=x**2+y**2
Note that the history commands will be saved up to, but not including the last value (i.e., history commands 13-16 saves commands 13, 14, and 15).

There are two mechanisms for searching command history:

1. Previous/Next: use Ctrl-p (previous, up) and Ctrl-n (next, down) to search through only the history items that match what you have typed so far (min-match completion). If you use Ctrl-p or Ctrl-n at a blank prompt, they behave just like the normal arrow keys.

2. Search: Ctrl-r opens a search prompt. Begin typing and the system searches your history for lines that contain what you’ve typed so far, completing what it can. For example:

   CASA [37]: <Cntl-r>

   (reverse-i-search)

   Typing anything after the colon will provide you with the last command matching the characters, for example, typing 'op' finds:

   (reverse-i-search)'op': im.open('ngc5921.ms')

   Subsequent hitting of Ctrl-r will search for the next command matching the characters.

### D.9 Macros

Macros can be made for easy re-execution of previous commands. For example to store the commands 13-15 to the macro 'example':

   CASA [31]: macro example 13:16
   Macro 'example' created. To execute, type its name (without quotes).
   Macro contents:
   x=1
   y=3*x
   z=x**2+y**2

   CASA [32]: z
   Out[32]: 6

   CASA [33]: z=10

   CASA [34]: example
   Out[34]: Executing Macro...
D.10 On-line editing

You can edit files on-line in two ways:

1. Using the shell access via '!vi'
2. Using the ed function; this will edit the file but upon closing, it will try to execute the file; using the 'script.py' example above:

```
CASA [13]: ed script.py # this will bring up the file in your chosen editor
       # when you are finished editing the file,
       # it will automatically
       # execute it (as though you had done a
       # execfile 'script.py'
       
Editing... done. Executing edited code...
```

D.11 Executing Python scripts

Python scripts are simple text files containing lists of commands as if typed at the keyboard. Note: the auto-parentheses feature of IPython can not be used in scripts, that is, you should make sure all function calls have any opening and closing parentheses.

```
# file is script.py
# My script to plot the observed visibilities
plotxy('ngc5921.ms','uvdist') #yaxis defaults to amplitude
```

This can be done by using the execfile command to execute this script. execfile will execute the script as though you had typed the lines at the CASA prompt.

```
CASA [5]: execfile 'script.py'
--------> execfile('script.py')
```
D.12 How do I exit from CASA?

You can exit CASA by using the `quit` command. This will bring up the query

```
Do you really want to exit ([y]/n)?
```

to give you a chance in case you did not mean to exit. You can also quit using `%exit` or `CTRL-D`.

If you don’t want to see the question "Do you really want to exit [y]/n?", then just type `Exit` or `exit` followed by return, and CASA will stop right then and there.
Appendix E

The Measurement Equation and Calibration

The visibilities measured by an interferometer must be calibrated before formation of an image. This is because the wavefronts received and processed by the observational hardware have been corrupted by a variety of effects. These include (but are not exclusive to): the effects of transmission through the atmosphere, the imperfect details amplified electronic (digital) signal and transmission through the signal processing system, and the effects of formation of the cross-power spectra by a correlator. Calibration is the process of reversing these effects to arrive at corrected visibilities which resemble as closely as possible the visibilities that would have been measured in vacuum by a perfect system. The subject of this chapter is the determination of these effects by using the visibility data itself.

E.1 The HBS Measurement Equation

The relationship between the observed and ideal (desired) visibilities on the baseline between antennas i and j may be expressed by the Hamaker-Bregman-Sault Measurement Equation:

\[
\vec{V}_{ij} = J_{ij} \vec{V}_{ij}^{\text{IDEAL}}
\]

where \( \vec{V}_{ij} \) represents the observed visibility, \( \vec{V}_{ij}^{\text{IDEAL}} \) represents the corresponding ideal visibilities, and \( J_{ij} \) represents the accumulation of all corruptions affecting baseline \( ij \). The visibilities are indicated as vectors spanning the four correlation combinations which can be formed from dual-polarization signals. These four correlations are related directly to the Stokes parameters which fully describe the radiation. The \( J_{ij} \) term is therefore a 4×4 matrix.

Most of the effects contained in \( J_{ij} \) (indeed, the most important of them) are antenna-based, i.e., they arise from measurable physical properties of (or above) individual antenna elements in a synthesis array. Thus, adequate calibration of an array of \( N_{\text{ant}} \) antennas forming \( N_{\text{ant}}(N_{\text{ant}} - 1)/2 \) baseline visibilities is usually achieved through the determination of only \( N_{\text{ant}} \) factors, such that

\( J_{ij} = J_i \otimes J_j^* \). For the rest of this chapter, we will usually assume that \( J_{ij} \) is factorable in this way, unless otherwise noted.

As implied above, \( J_{ij} \) may also be factored into the sequence of specific corrupting effects, each having their own particular (relative) importance and physical origin, which determines their unique algebra. Including the most commonly considered effects, the Measurement Equation can be written:

\[
\vec{V}_{ij} = M_{ij} B_{ij} G_{ij} D_{ij} E_{ij} P_{ij} T_{ij} \vec{V}_{ij}^{\text{IDEAL}}
\]

where:

- \( T_{ij} \) = Polarization-independent multiplicative effects introduced by the troposphere, such as opacity and path-length variation.
- \( P_{ij} \) = Parallactic angle, which describes the orientation of the polarization coordinates on the plane of the sky. This term varies according to the type of the antenna mount.
- \( E_{ij} \) = Effects introduced by properties of the optical components of the telescopes, such as the collecting area’s dependence on elevation.
- \( D_{ij} \) = Instrumental polarization response. "D-terms" describe the polarization leakage between feeds (e.g. how much the R-polarized feed picked up L-polarized emission, and vice versa).
- \( G_{ij} \) = Electronic gain response due to components in the signal path between the feed and the correlator. This complex gain term \( G_{ij} \) includes the scale factor for absolute flux density calibration, and may include phase and amplitude corrections due to changes in the atmosphere (in lieu of \( T_{ij} \)). These gains are polarization-dependent.
- \( B_{ij} \) = Bandpass (frequency-dependent) response, such as that introduced by spectral filters in the electronic transmission system
- \( M_{ij} \) = Baseline-based correlator (non-closing) errors. By definition, these are not factorable into antenna-based parts.

Note that the terms are listed in the order in which they affect the incoming wavefront (\( G \) and \( B \) represent an arbitrary sequence of such terms depending upon the details of the particular electronic system). Note that \( M \) differs from all of the rest in that it is not antenna-based, and thus not factorable into terms for each antenna.

As written above, the measurement equation is very general; not all observations will require treatment of all effects, depending upon the desired dynamic range. E.g., bandpass need only be considered for continuum observations if observed in a channelized mode and very high dynamic range is desired. Similarly, instrumental polarization calibration can usually be omitted when observing (only) total intensity using circular feeds. Ultimately, however, each of these effects occurs at some level, and a complete treatment will yield the most accurate calibration. Modern high-sensitivity instruments such as ALMA and EVLA will likely require a more general calibration.
treatment for similar observations with older arrays in order to reach the advertised dynamic ranges on strong sources.

In practice, it is usually far too difficult to adequately measure most calibration effects absolutely (as if in the laboratory) for use in calibration. The effects are usually far too changeable. Instead, the calibration is achieved by making observations of calibrator sources on the appropriate timescales for the relevant effects, and solving the measurement equation for them using the fact that we have $N_{\text{ant}}(N_{\text{ant}} - 1)/2$ measurements and only $N_{\text{ant}}$ factors to determine (except for $M$ which is only sparingly used). (Note: By partitioning the calibration factors into a series of consecutive effects, it might appear that the number of free parameters is some multiple of $N_{\text{ant}}$, but the relative algebra and timescales of the different effects, as well as the the multiplicity of observed polarizations and channels compensate, and it can be shown that the problem remains well-determined until, perhaps, the effects are direction-dependent within the field of view. Limited solvers for such effects are under study; the calibrator tool currently only handles effects which may be assumed constant within the field of view. Corrections for the primary beam are handled in the imager tool.) Once determined, these terms are used to correct the visibilities measured for the scientific target. This procedure is known as cross-calibration (when only phase is considered, it is called phase-referencing).

The best calibrators are point sources at the phase center (constant visibility amplitude, zero phase), with sufficient flux density to determine the calibration factors with adequate SNR on the relevant timescale. The primary gain calibrator must be sufficiently close to the target on the sky so that its observations sample the same atmospheric effects. A bandpass calibrator usually must be sufficiently strong (or observed with sufficient duration) to provide adequate per-channel sensitivity for a useful calibration. In practice, several calibrators are usually observed, each with properties suitable for one or more of the required calibrations.

Synthesis calibration is inherently a bootstrapping process. First, the dominant calibration term is determined, and then, using this result, more subtle effects are solved for, until the full set of required calibration terms is available for application to the target field. The solutions for each successive term are relative to the previous terms. Occasionally, when the several calibration terms are not sufficiently orthogonal, it is useful to re-solve for earlier types using the results for later types, in effect, reducing the effect of the later terms on the solution for earlier ones, and thus better isolating them. This idea is a generalization of the traditional concept of self-calibration, where initial imaging of the target source supplies the visibility model for a re-solve of the gain calibration ($G$ or $T$). Iteration tends toward convergence to a statistically optimal image. In general, the quality of each calibration and of the source model are mutually dependent. In principle, as long as the solution for any calibration component (or the source model itself) is likely to improve substantially through the use of new information (provided by other improved solutions), it is worthwhile to continue this process.

In practice, these concepts motivate certain patterns of calibration for different types of observation, and the calibrator tool in CASA is designed to accommodate these patterns in a general and flexible manner. For a spectral line total intensity observation, the pattern is usually:

1. Solve for $G$ on the bandpass calibrator
2. Solve for $B$ on the bandpass calibrator, using $G$
3. Solve for \( G \) on the primary gain (near-target) and flux density calibrators, using \( B \) solutions just obtained.

4. Scale \( G \) solutions for the primary gain calibrator according to the flux density calibrator solutions.

5. Apply \( G \) and \( B \) solutions to the target data.

6. Image the calibrated target data.

If opacity and gain curve information are relevant and available, these types are incorporated in each of the steps (in future, an actual solve for opacity from appropriate data may be folded into this process):

1. Solve for \( G \) on the bandpass calibrator, using \( T \) (opacity) and \( E \) (gain curve) solutions already derived.

2. Solve for \( B \) on the bandpass calibrator, using \( G \), \( T \) (opacity), and \( E \) (gain curve) solutions.

3. Solve for \( G \) on primary gain (near-target) and flux density calibrators, using \( B \), \( T \) (opacity), and \( E \) (gain curve) solutions.

4. Scale \( G \) solutions for the primary gain calibrator according to the flux density calibrator solutions.

5. Apply \( T \) (opacity), \( E \) (gain curve), \( G \), and \( B \) solutions to the target data.

6. Image the calibrated target data.

For continuum polarimetry, the typical pattern is:

1. Solve for \( G \) on the polarization calibrator, using (analytical) \( P \) solutions.

2. Solve for \( D \) on the polarization calibrator, using \( P \) and \( G \) solutions.

3. Solve for \( G \) on primary gain and flux density calibrators, using \( P \) and \( D \) solutions.

4. Scale \( G \) solutions for the primary gain calibrator according to the flux density calibrator solutions.

5. Apply \( P \), \( D \), and \( G \) solutions to target data.

6. Image the calibrated target data.

For a spectro-polarimetry observation, these two examples would be folded together.

In all cases the calibrator model must be adequate at each solve step. At high dynamic range and/or high resolution, many calibrators which are nominally assumed to be point sources become slightly resolved. If this has biased the calibration solutions, the offending calibrator may be imaged at any point in the process and the resulting model used to improve the calibration. Finally, if sufficiently strong, the target may be self-calibrated as well.
E.2 General Calibrater Mechanics

The calibrater tasks/tool are designed to solve and apply solutions for all of the solution types listed above (and more are in the works). This leads to a single basic sequence of execution for all solves, regardless of type:

1. Set the calibrator model visibilities
2. Select the visibility data which will be used to solve for a calibration type
3. Arrange to apply any already-known calibration types (the first time through, none may yet be available)
4. Arrange to solve for a specific calibration type, including specification of the solution timescale and other specifics
5. Execute the solve process
6. Repeat 1-4 for all required types, using each result, as it becomes available, in step 2, and perhaps repeating for some types to improve the solutions

By itself, this sequence doesn’t guarantee success; the data provided for the solve must have sufficient SNR on the appropriate timescale, and must provide sufficient leverage for the solution (e.g., D solutions require data taken over a sufficient range of parallactic angle in order to separate the source polarization contribution from the instrumental polarization).
Appendix F

Annotated Example Scripts

Note: These data sets are available with the full CASA rpm distribution. Other data sets can be made available upon request. The scripts are intended to illustrate the types of commands needed for different types of reduction/astronomical observations.

BETA ALERT: During the Beta Release period, we will be occasionally updating the syntax of the tasks, which may break older versions of the scripts. You can find the latest versions of these (and other) scripts at:

F.1 NGC 5921 — VLA red-shifted HI emission

This script demonstrates basic spectral calibration and imaging, but does not include any self-calibration steps.

The latest version of this script can be found at:

# F.3  BIMA Mosaic Spectral Imaging 

This script analyzes a BIMA SONG mosaic of the galaxy NGC 4826 at 3mm. The latest version of this script can be found at:

http://casa.nrao.edu/Doc/Scripts/ngc4826_tutorial.py
# Updated by CB 2009-05-18 immoments axis=spectral #
# Updated by CB 2009-05-19 added restfreq to clean #
# Updated by CB 2009-05-19 removed clearcals #
#
# N4826 - BIMA SONG Data
#
# This data is from the BIMA Survey of Nearby Galaxies (BIMA SONG)
# Many thanks to Michele Thornley for providing the data and description
#
# First day of observations only
#
# Script Notes:
# o The "default" commands are not necessary, but are included
#  in case we want to change from function calls to globals
# o This script has some interactive commands, such as with plotxy
#  and the viewer. This script will stop and require a
#  carriage-return to continue at these points.
# o Sometimes cut-and-paste of a series of lines from this script
#  into the casapy terminal will get garbled (usually a single
#  dropped character). In this case, try fewer lines, like groups
#  of 4-6.

#
##########################################################################
#
# TUTORIAL NOTES:
#
# You can invoke tasks in two ways:
#
# (1) As function calls with arguments as shown above for concat and used
#
extensively in this script, e.g.
#
#
task( par1=val1, par2=val2, ... )
#
#
with parameters set as arguments in the call. Note that in this
#
case, the global parameter values are NOT used or changed, and any
#
task parameters that are not specified as arguments to the call
#
will be defaulted to the task-specific default values (see the
#
"help task" description).
#
# (2) By setting the values of the global parameters and then using the
#
"go" command (if taskname is set) or calling the task with no
#
arguments. For example:
#
#
default task
#
par1 = val1
#
par2 = val2
#
...
#
inp
#
task()
#
#
In this case, the "default" command sets the parmeters to their
#
task defaults, and sets the "taskname" paramter to the task to be
#
run. The "inp" command displays the current values for the task

456


# parameters. Then the call with no arguments runs with the globals.
#
# Warning: "go" does not work inside scripts. See Cookbook.
#
# Using the concat call above as an example, we would do:
#
#default('concat')
#
# vis = ['ngc4826.tutorial.3c273.5.ms',
#       'ngc4826.tutorial.3c273.6.ms',
#       'ngc4826.tutorial.3c273.7.ms',
#       'ngc4826.tutorial.3c273.8.ms',
#       'ngc4826.tutorial.1310+323.ll.9.ms',
#       'ngc4826.tutorial.1310+323.ll.10.ms',
#       'ngc4826.tutorial.1310+323.ll.11.ms',
#       'ngc4826.tutorial.1310+323.ll.12.ms',
#       'ngc4826.tutorial.1310+323.ll.13.ms',

# Plotting and Flagging

# The plotxy task is the interactive x-y display and flagging GUI

print '--Plotxy--'
default(plotxy)

# Here we will suggest things to plot, and actually only do a few
# (near the end of this task block). If you like you can
# uncomment these when you run this script
#
# First look at amplitude as a function of uv-distance using an
# average over all channels for each source.
#
# Interactive plotxy
#plotxy(vis='ngc4826.tutorial.ms',xaxis='uvdist',yaxis='amp',field='0',spw='0-3',
# averagemode='vector',width='1000',
# selectplot=True,title='Field 0 SPW 0-3')
#
# Pause script if you are running in scriptmode
#user_check=raw_input('Return to continue script\n')

# NOTE: width here needs to be larger than combination of all channels
# selected with spw and/or field. Since field and spw are unique in this
# case, both don't need to be specified, however plotting is much faster
# if you "help it" by selecting both.
#
# Now average over all times across scans but not over channel and
# plot versus channel. There are four 64-channel spws set end-to-end
# by plotxy You should see bad edge channels in each spw segment We
# will flag these (non-interactively) later
#
# Interactive plotxy
plotxy(vis='ngc4826.tutorial.ms', xaxis='channel', yaxis='amp', field='0', spw='0~3',
   # averagemode='vector', timebin='1e7', crossscans=True,
   # selectplot=True, newplot=False, title='Field 0 SPW 0~3')
#
# Pause script if you are running in scriptmode
user_check=raw_input('Return to continue script\n')

# You can also plot versus velocity by setting xaxis='velocity'
#
# You might do this for all the other spw/field combos
#
# You can also non-interactively plotxy to a file
# (note this works only if iteration is not set)
# Also, see how we use Python variables to make this easier
#
# field = '0'
# spw = '0~3'
# figfile = 'ngc4826.tutorial.ms' + '.plotxy.'+field+'.spectrum.raw.png'
plotxy(vis='ngc4826.tutorial.ms', xaxis='velocity', yaxis='amp', field=field, spw=spw,
   # averagemode='vector', timebin='1e7', crossscans=True,
   # selectplot=True, newplot=False, title='Field '+field+' SPW '+spw,
   # interactive=False, figfile=figfile)

# Now lets look at the target source, the first of the NGC4826 mosaic fields
# which are 2~8 in this MS.
#
# Since we are plotting versus velocity we can clearly see the bad edge
# channels and the overlap between spw
#
# There is nothing terribly wrong with this data and again we will flag the
# edge channels non-interactively later for consistency.
#
# Normally, if there were obviously bad data, you would flag it here
# before calibration. To do this, hit the Mark Region button, then draw a box around
# some of the moderately high outliers, and then Flag.
#
# But this data is relatively clean, and flagging will not improve results.
#
# Interactive plotxy
plotxy(vis='ngc4826.tutorial.ms', xaxis='velocity', yaxis='amp', field='2', spw='12~15',
   averagemode='vector', timebin='1e7', crossscans=True,
   selectplot=True, newplot=False, title='Field 2 SPW 12~15')

print "You could Mark Region around outliers and Flag"
# Pause script if you are running in scriptmode
user_check=raw_input('Return to continue script\n')

# You could set up a Python loop to do all the N4826 fields, like this:
#for fld in range(2,9):
# field = str(fld)
# plotxy(vis='ngc4826.tutorial.ms',xaxis='velocity',yaxis='amp',field=field,spw=spw,
# averagemode='vector',timebin='1e7',crossscans=True,
# selectplot=True,newplot=False,title='Field '+field+' SPW '+spw)
#
# print "Nominally, Mark Region around outliers and Flag"
# # Pause script if you are running in scriptmode
# user_check=raw_input('Return to continue script\n')
#
# Back to first field.
# You can also have it iterate over baselines, using Next to advance
# ignore baselines 1:1, 2:2 etc. as they would correspond to autocorrelations
# if they were present (they are not in this dataset)
#
# Interactive plotxy
#plotxy(vis='ngc4826.tutorial.ms',xaxis='channel',yaxis='amp',field='0',spw='0~3',
# averagemode='vector',timebin='1e7',crossscans=True,
# iteration='baseline',
# selectplot=True,newplot=False,title='Field 0 SPW 0~3')
#
# Pause script if you are running in scriptmode
#user_check=raw_input('Return to continue script\n')
#
# Finally, look for bad data. Here we look at field 8 w/o averaging
plotxy(vis='ngc4826.tutorial.ms',xaxis='time',yaxis='amp',field='8',spw='12~15',
# selectplot=True,newplot=False,title='Field 8 SPW 12~15')
print "You can see some bad data here"
print "Mark Region and Locate, look in logger"
print "This is a correlator glitch in baseline 3-9 at 06:19:30"

#
#
##########################################################################
# IMAGING OF NGC4826 MOSAIC
#
##########################################################################
# Mosaic field spacing looks like:
# F3 (field 3)  F2 (field 2)
# F4 (field 4)  F0 (field 0)  F1 (field 1)
# F5 (field 5)    F6 (field 6)
#
# 4x64 channels = 256 channels
#
# Primary Beam should be about 1.6' FWHM (7m dishes, 2.7mm wavelength)
# Resolution should be about 5-8"
##########################################################################
#
# Image the target source mosaic:
#
# print 'Clean (NGC4826)--'
default('clean')

    clean(vis='ngc4826.tutorial.16apr98.src.split.ms',
          imagename='ngc4826.tutorial.16apr98.src.clean',
          field='0~6',spw='0~3',
          cell=[1.,1.],imsize=[256,256],stokes='I',
          mode='channel',nchan=36,start=35,width=4,
          psfmode='clark',imagermode='mosaic',scaletype='SAULT',
          niter=10000,threshold='45mJy',
          restfreq='115.2712GHz',interactive=F,
          minpb=0.3,pbcor=False)

### NOTE: Sault weighting implies a uniform noise mosaic
### NOTE: that niter is set to large number so that stopping point is
### controlled by threshold.
### NOTE: with pbcor=False, the final image is not "flux correct",
### instead the image has constant noise despite roll off in power as
### you move out from the phase center(s). Though this format makes it
### "look nicest", for all flux density measurements, and to get an
### accurate integrated intensity image, one needs to divide the
### srcimage.image/srcimage.flux in order to correct for the mosaic
### response pattern. One could also achieve this by setting pbcor=True
### in clean.

# Try running clean adding the parameter interactive=True.
# This parameter will periodically bring up the viewer to allow
# interactive clean boxing. For poor uv-coverage, deep negative bowls
# from missing short spacings, this can be very important to get correct
# integrated flux densities.

print "Found moment 0 rms = "+str(momzerostat['rms'][0])

momonestat=imstat('ngc4826.tutorial.16apr98.moments.mom1')

print "Found moment 1 median = "+str(momonestat['median'][0])
#
##########################################################################

# An alternative is to mask the pbcor image before calculating
# moments. The following block shows how to do this.

#print '--Viewer--'
#viewer(ngc4826.tutorial.16apr98.moments.integrated)

# TUTORIAL NOTES: After loading change "unit contour level" in "Data
# Display Options" gui to something like 70. select "region manager
# tool" from "tool" drop down menu Then assign the sqiggly Polygon
# button to a mouse button by clicking on it with a mouse button. Then
# draw a polygon region around galaxy emission, avoiding edge regions
# and double click in the region you created. Then in "region manager
# tool" select "save to file" and give file name mom0mask.rgn.
# print '--ImMoments (masked)--'
# print 'Creating masked moment 0 image ngc4826.tutorial.16apr98.moments.integratedmasked'
# immoments(imagename='ngc4826.tutorial.16apr98.src.clean.pbcor',
#    moments=0, axis='spectral',
#    chans='7~28', region='mom0mask.rgn',
#    outfile='ngc4826.tutorial.16apr98.moments.integratedmasked')
#
# print 'Creating masked moment 1 image ngc4826.tutorial.16apr98.moments.mom1masked'
# immoments(imagename='ngc4826.tutorial.16apr98.src.clean.pbcor.masked',
#    moments=1, axis='spectral',
#    includepix=[0.2,1000.0],
#    chans='7~28', region='mom0mask.rgn',
#    outfile='ngc4826.tutorial.16apr98.moments.mom1masked')
#
# Now view the resulting images
# viewer('ngc4826.tutorial.16apr98.moments.integratedmasked')
#
# print "Now viewing masked Moment-0 ngc4826.tutorial.16apr98.moments.integratedmasked"
# print "You can Open and overlay Contours of Moment-1 ngc4826.tutorial.16apr98.moments.mom1masked"
#
# Pause script if you are running in scriptmode
# user_check=raw_input('Return to continue script\n')
#
# Finally, can compute and print statistics
# print '--ImStat (masked moments)--'
# maskedmomzerostat = imstat('ngc4826.tutorial.16apr98.moments.integratedmasked')
# print "Found masked moment 0 max = \"+str(maskedmomzerostat['max'][0])\"

Appendix G

CASADictionaries

BETA ALERT: These tend to become out of date as we add new tasks or change names.

G.1 AIPS – CASA dictionary

Please see:

- https://wikio.nrao.edu/bin/view/Software/CASA-AIPSDictionary

BETA ALERT: This link is out-of-date and refers mostly to the Toolkit. We will update this with a task dictionary.

G.2 MIRIAD – CASA dictionary

Table G.1 provides a list of common Miriad tasks, and their equivalent CASA tool or tool function names. The two packages differ in both their architecture and calibration and imaging models, and there is often not a direct correspondence. However, this index does provide a scientific user of CASA who is familiar with MIRIAD, with a simple translation table to map their existing data reduction knowledge to the new package.

G.3 CLIC – CASA dictionary

Table G.2 provides a list of common CLIC tasks, and their equivalent CASA tool or tool function names. The two packages are very similar since the CASA software to reduce IRAM data is based on the CLIC reduction procedures.
Table G.1: MIRIAD – CASA dictionary

Appendix H

Writing Tasks

**BETA ALERT:** This prescription for writing and incorporating tasks in CASA is for the power-user. This procedure is also likely to change in future releases.

It is possible to write your own task and have it appear in casapy. You must create two files, yourtask.xml and a task_yourtask.py. The xml file is use to describe the interface to the task and the task_yourtask.py does the actual work. The argument names must be the same in both the yourtask.xml and task_yourtask.py file. The yourtask.xml file is used to generated all the interface files so yourtask will appear in the casapy system.

Synopsis

- buildmytasks yourtask
- execfile 'PATH_TO_YOURTASK/yourtask.py (from inside casapy)'

H.1 The XML file

The key to getting your task into casapy is constructing a task interface description XML file.

Some XML basics, an xml element begins with `<element>` and ends with `</element>`. If an XML element contains no other XML element you may specify it via `<element/>`. An XML element may have zero or more attributes which are specified by attribute="attribute value". You must put the attribute value in quotes, i.e. `<element myattribute="attribute value"/>`.

All task xml files must start with this header information.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet type="text/xsl" ?>
<casaxml xmlns="http://casa.nrao.edu/schema/psetTypes.html"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://casa.nrao.edu/schema/casa.xsd"
```
and the file must have the end tag

</casaxml>

Inside a <task> tags you will need to specify the following elements.

<task>

**Attributes**
- type required, allowed value is "function"
- name required

**Subelements**
- shortdescription required
- description required
- input optional
- output optional
- returns optional
- constraints optional

**<shortdescription>** - required by <task>; A short one-line description describing your task

**Attributes**
- None

**Subelements**
- None

**<description>** - required] by <task>, Also used by <param>a; A longer description describing your task with multiple lines

**Attributes**
- None

**Subelements**
- None

**<input>** - optional element used by <task>; An input block specifies which parameters are used for input

**Attributes**
- None

**Subelements**
<param>, optional

<output> - optional  An output element that contains a list of parameters that are ”returned” by the task.

Attributes
None

Subelements
<param>, optional

<returns> - optional  Value returned by the task

Attributes
None

Subelements
<description>, optional

<constraints> - optional  A constraints element that lets you constrain params based on the values of other params.

Attributes
None

Subelement
<when>, required.

<param> - optional  The input and output elements consist of param elements.

Attributes
    type, required; allowed values are record, variant, string int, double, bool, intArray, doubleArray, boolArray, stringArray
    name, required;
    subparam, optional; allowed values True, False, Yes or No.
    kind, optional;
    mustexist, optional; allowed values True, False, Yes or No.

All param elements require name and type attributes.

Subelements
<description>, required;
<value>, optional;
<allowed>, optional;

<value> - optional  Value returned by the task

Attributes
    type, required; as specified in <param> attributes.
Subelements
    <value>, optional

<allowed> - optional; Block of allowed values

Attributes
    enum, required; maybe enum or range. If specified as enum only specific values are allowed. If specified as range then the value tags may have min and max attributes.

Subelements
    <value>, optional

<when> - optional When blocks allow value specific handling for parameters

Attributes
    param, required; Specifies special handling for a <param>

Subelements
    <equals>, optional
    <notequals>, optional

<equals> - optional Reset parameters if equal to the specified value

Attributes
    value, required; the value of the parameter

Subelements
    <default>, required

<notequals> - optional Reset specified parameters if not equal to the specified value

Attributes
    value, required; The value of the parameter

Subelements
    <default>, optional

<default> - optional Resets default values for specified parameters

Attributes
    param, required; Name of the <param> to be reset.

Subelements
    <value>, required, the revised value of the <param>.

<example> - optional An example block, typically in python

Attributes
    lang optional; specifies the language of the example, defaults to python.

Subelements
    None
H.2 The task_yourtask.py file

You must write the Python code that does the actual work. The task_*_.py file function call sequence must be the same as specified in the XML file. We may relax the requirement that the function call sequence exactly match the sequence in the XML file in a future release.

H.3 Example: The clean task

H.3.1 File clean.xml

Clean.xml gives a fairly comprehensive example of how to construct the XML file.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet type="text/xsl" ?>
<casaxml xmlns="http://casa.nrao.edu/schema/psetTypes.html"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://casa.nrao.edu/schema/casa.xsd
file:///opt/casa/code/xmlcasa/xml/casa.xsd">

<!-- This is the param set for clean -->
<!-- This does the equivalent of -->
<!-- imgr:=imager('anyfile.ms'); -->
<!-- imgr.setdata(mode='channel',nchan=100,start=1,step=1,fieldid=1) -->
<!-- imgr.setimage(nx=512,ny=,cellx='1arcsec',celly='1arcsec',stokes='I', -->
<!-- mode='channel',start=35,step=1,nchan=40, -->
<!-- fieldid=[1]) -->
<!-- imgr.weight('natural'); -->
<!-- imgr.clean(algorithm='csclena',niter=500,model='field1') -->

<task type="function" name="clean">

<shortdescription>Deconvolve an image with selected algorithm</shortdescription>

<description>
Form images from visibilities. Handles continuum and spectral line cubes.
</description>

<input>

<param type="string" name="vis" kind="ms" mustexist="true">

<returns type="void"/>

<example>

The main clean deconvolution task. It contains many functions

1) Make 'dirty' image and 'dirty' beam (psf)
2) Multi-frequency-continuum images or spectral channel imaging
3) Full Stokes imaging
4) Mosaicking of several pointings
5) Multi-scale cleaning
6) Interactive clean boxing
7) Initial starting model

vis -- Name of input visibility file
    default: none; example: vis='ngc5921.ms'
imagename -- Pre-name of output images:
    default: none; example: imagename='m2'
output images are:
    m2.image; cleaned and restored image
With or without primary beam correction
m2.psf; point-spread function (dirty beam)
m2.flux; relative sky sensitivity over field
m2.model; image of clean components
m2.residual; image of residuals
m2.interactive.mask; image containing clean regions

field -- Select fields in mosaic. Use field id(s) or field name(s).
    ['go listobs' to obtain the list id's or names]
default: ''=all fields
If field string is a non-negative integer, it is assumed to
    be a field index otherwise, it is assumed to be a

field name
    field='0~2'; field ids 0,1,2
    field='0,4,5~7'; field ids 0,4,5,6,7
    field='3C286,3C295'; field named 3C286 and 3C295
    field = '3,4C*'; field id 3, all names starting with 4C

spw -- Select spectral window/channels
    NOTE: This selects the data passed as the INPUT to mode
default: ''=all spectral windows and channels
    spw='0~2,4'; spectral windows 0,1,2,4 (all channels)
    spw='0:5~61'; spw 0, channels 5 to 61
    spw='&lt;2'; spectral windows less than 2 (i.e. 0,1)
    spw='0,10,3:3~45'; spw 0,10 all channels, spw 3,
    channels 3 to 45.
    spw='0~2:2~6'; spw 0,1 with channels 2 through 6 in each.
    spw='0~10;15~60'; spectral window 0 with channels
0~10,15~60
    spw='0~10,1:20~30,2:1;2;3'; spw 0, channels 0-10,
    spw 1, channels 20-30, and spw 2, channels, 1,2 and 3

selectdata -- Other data selection parameters
default: True

See help par.selectdata for more on these

timerange -- Select data based on time range:
default = '' (all); examples,
timerange = 'YYYY/MM/DD/hh:mm:ss~YYYY/MM/DD/hh:mm:ss'
    Note: if YYYY/MM/DD is missing date defaults to first
day in data set
timerange='09:14:0~09:54:0' picks 40 min on first day
timerange = '25:00:00~27:30:00' picks 1 hr to 3 hr
30min on NEXT day
timerange='09:44:00' pick data within one integration
timerange='&gt;10:24:00' data after this time

uvrange -- Select data within uvrange (default units meters)
default: '' (all); example:
uvrange='0~1000klambda'; uvrange from 0-1000 kilo-lambda
uvrange='>4klambda'; uvranges greater than 4 kilo lambda

antenna -- Select data based on antenna/baseline
  default: '' (all)
  If antenna string is a non-negative integer, it is
  assumed to be an antenna index, otherwise, it is
  considered an antenna name.
  antenna='5&6'; baseline between antenna index 5 and
  index 6.
  antenna='VA05&VA06'; baseline between VLA antenna 5
  and 6.
  antenna='5&6;7&8'; baselines 5-6 and 7-8
  antenna='5'; all baselines with antenna index 5
  antenna='05'; all baselines with antenna number 05
(VLA old name)
  antenna='5,6,9'; all baselines with antennas 5,6,9

index numbers

scan -- Scan number range.
  default: '' (all)
  example: scan='1~5'
  Check 'go listobs' to insure the scan numbers are in
  order.

mode -- Frequency Specification:
  NOTE: See examples below:
  default: 'mfs'
  mode = 'mfs' means produce one image from all
  specified data.
  mode = 'channel'; Use with nchan, start, width to specify
  output image cube. See examples below
  mode = 'velocity', means channels are specified in
  velocity.
  mode = 'frequency', means channels are specified in
  frequency.

&>&>&: mode expandable parameters (for modes other than 'mfs')
  Start, width are given in units of channels, frequency
  or velocity as indicated by mode, but only channel
  is complete.

nchan -- Number of channels (planes) in output image
  default: 1; example: nchan=3
start -- Start input channel (relative-0)
  default=0; example: start=5
width -- Output channel width in units of the input
  channel width (&:1 indicates channel averaging)
  default=1; example: width=4

examples:
spw = '0,1'; mode = 'mfs'
will produce one image made from all channels in spw 0 and 1

spw='0:5~28^2'; mode = 'mfs'
will produce one image made with channels (5,7,9,...,25,27)

spw = '0'; mode = 'channel'; nchan=3; start=5; width=4
will produce an image with 3 output planes
plane 1 contains data from channels (5+6+7+8)
plane 2 contains data from channels (9+10+11+12)
plane 3 contains data from channels (13+14+15+16)

spw = '0:0~63^3'; mode='channel'; nchan=21; start = 0; width = 1
will produce an image with 20 output planes
Plane 1 contains data from channel 0
Plane 2 contains data from channel 2
Plane 21 contains data from channel 61

spw = '0:0~40^2'; mode = 'channel'; nchan = 3; start = 5; width = 4
will produce an image with three output planes
plane 1 contains channels (5,7)
plane 2 contains channels (13,15)
plane 3 contains channels (21,23)

psfmode -- method of PSF calculation to use during minor cycles:
default: 'clark': Options: 'clark','hogbom'
'clark' use smaller beam (faster, usually good enough)
'hogbom' full-width of image (slower, better for poor uv-coverage)

Note: psfmode will be used to clean is imagermode = ''
imagermode -- Advanced imaging e.g mosaic or Cotton-Schwab clean
default: imagermode='': Options: '', 'csclean', 'mosaic'
default '' =&gt; psfmode cleaning algorithm used
&gt;&gt;&gt; imagermode='mosaic' expandable parameter(s):
Image as a mosaic of the different pointings (uses csclean style too)

mosweight -- Individually weight the fields of the mosaic
default: False; example: mosweight=True
This can be useful if some of your fields are more sensitive than others (i.e. due to time spent on-source); this parameter will give more weight to higher sensitivity fields in the overlap regions.

ftmachine -- Gridding method for the image;
Options: ft (standard interferometric gridding), sd (standard single dish) both (ft and sd as appropriate), mosaic (gridding use PB as convolution function)
scaletype -- Controls scaling of pixels in the image plane.
(Not fully implemented...for now only controls what is seen if interactive=True...but in the future will control the image on which clean components are searched)
default='SAULT'; example: scaletype='PBCOR'
Options: 'PBCOR','SAULT'
'SAULT' when interactive=True shows the residual with constant noise across the mosaic. If pbcor=False, the final output image is NOT corrected for the PB pattern, and therefore is not "flux correct". Division of SAULT &lt;imagename&gt;.image by the &lt;imagename&gt;.flux image will produce a "flux correct image", can also be acheived by setting pbcor=True.

'PBCOR' uses the SAULT scaling scheme for deconvolution, but if interactive=True shows the primary beam corrected image; the final PBCOR image is "flux correct" if pbcor=True.

imagermode='csclean' expandable parameter(s): Image using the Cotton-Schwab algorithm in between major cycles
cyclefactor -- Change the threshold at which the deconvolution cycle will stop, degrid and subtract from the visibilities. For poor PSFs, reconcile often (cyclefactor=4 or 5); For good PSFs, use cyclefactor 1.5 to 2.0. Note: threshold = cyclefactor * max sidelobe * max residual.
default: 1.5; example: cyclefactor=4
cyclespeedup -- Cycle threshold doubles in this number of iterations default: -1;
example: cyclespeedup=3

try cyclespeedup = 50 to speed up cleaning

multiscale -- set of scales to use in deconvolution. If set, cleans with several resolutions using hobgom clean. The scale sizes are in units of cellsize. So if cell='2arcsec', a multiscale scale=10 = 20arcsec. First scale should always be 0 (point), we suggest second on the order of synthesized beam, third 3-5 times synthesized beam, etc. For example if synthesized beam is 10" and cell=2", try multiscale = [0,5,15]. Note, multiscale is currently a bit slow.
default: multiscale=[] (standard CLEAN using psfmode algorithm, no multi-scale). Example: multiscale = [0,5,15]
component search when the largest scale has found this number of negative components; -1 means continue component search even if the largest component is negative. default: -1; example: negcomponent=50

**imsize** -- Image pixel size (x,y)
default = [256,256]; example: imsize=[350,350]
imsize = 500 is equivalent to [500,500]

**cell** -- Cell size (x,y)
default= '1.0arcsec';
example: cell=[['0.5arcsec','0.5arcsec']] or
cell=['1arcmin', '1arcmin']
cell = '1arcsec' is equivalent to ['1arcsec','1arcsec']
NOTE:cell = 2.0 =&gt; ['2arcsec', '2arcsec']

**phasecenter** -- direction measure or fieldid for the mosaic center
default: '' =&gt; first field selected ; example: phasecenter=6
or phasecenter='J2000 19h30m00 -40d00m00'

**restfreq** -- Specify rest frequency to use for output image
default='' Occasionally it is necessary to set this (for example some VLA spectral line data). For example for NH_3 (1,1) put restfreq='23.694496GHz'

**stokes** -- Stokes parameters to image
default='I'; example: stokes='IQUV';
Options: 'I','IV''QU','IQUV','RR','LL','XX','YY','RRLL','XXYY'

**niter** -- Maximum number iterations,
if niter=0, then no CLEANing is done ("invert" only)
default: 500; example: niter=5000

gain -- Loop gain for CLEANing
default: 0.1; example: gain=0.5

**threshold** -- Flux level at which to stop CLEANing
default: '0.0mJy';
example: threshold='2.3mJy' (always include units)
threshold = '0.0023Jy'
threshold = '0.0023Jy/beam' (okay also)

**interactive** -- use interactive clean (with GUI viewer)
default: interactive=False
example: interactive=True

interactive clean allows the user to build the cleaning mask interactively using the viewer. The viewer will appear every npercycle iteration, but modify as needed. The final interactive mask is saved in the file imagename_interactive.mask. The initial masks use the union of mask and cleanbox (see below)

**npercycle** -- this is the number of iterations between each clean to update mask interactively. Set to about niter/5, but can also be
changed interactively.

mask -- Specification of cleanbox(es), mask image(s), and/or region(s) to be used for CLEANing. As long as the image has the same shape (size), mask images from a previous interactive session can be used for a new execution. NOTE: the initial clean mask actually used is the union of what is specified in mask and &lt;imagename&gt;.mask default: [] (no masking); Possible specification types: (a) Explicit cleanbox pixel ranges example: mask=[110,110,150,145] clean region with blc=110,100; trc=150,145 (pixel values) (b) Filename with cleanbox pixel values with ascii format: example: mask='mycleanbox.txt' &lt;fieldid blc-x blc-y trc-x trc-y&gt; on each line
1 45 66 123 124
2 23 100 300 340
(c) Filename for image mask example: mask='myimage.mask'
(d) Filename for region specification (e.g. from viewer) example: mask='myregion.rgn' (e) Combinations of any of the above example: mask=[[110,110,150,145], 'mycleanbox.txt', 'myimage.mask', 'myregion.rgn']

uvtaper -- Apply additional uv tapering of the visibilities. default: uvtaper=False; example: uvtaper=True &gt;&gt;&gt; uvtaper=True expandable parameters
outertaper -- uv-taper on outer baselines in uv-plane [bmaj, bmin, bpa] taper Gaussian scale in uv or angular units. NOTE: uv taper in (klambda) is roughly on-sky FWHM(arcsec/200)
default: outertaper=[]; no outer taper applied example: outertaper=['5klambda'] circular taper FWHM=5 kilo-lambda
outertaper=['5klambda', '3klambda', '45.0deg']
outertaper=['10arcsec'] on-sky FWHM 10"
outertaper=['300.0'] default units are meters in aperture plane
innertaper -- uv-taper in center of uv-plane [bmaj,bmin,bpa] Gaussian scale at which taper falls to zero at uv=0
default: innertaper=[]; no inner taper applied NOT YET IMPLEMENTED
modelimage -- Name of model image(s) to initialize cleaning. If multiple images, then these will be added together to form initial staring model NOTE: these are in addition to any initial model in the &lt;imagename&gt;.model image file default: '' (none); example: modelimage='orion.model'
modelimage=[['orion.model', 'sdorion.image']] Note: if the
units in the image are Jy/beam as in a single-dish image, then it will be converted to Jy/pixel as in a model image, using the restoring beam in the image header.

weighting -- Weighting to apply to visibilities:
  default='natural'; example: weighting='uniform';
  Options: 'natural','uniform','briggs',
           'superuniform','briggsabs','radial'

For weighting='briggs' and 'briggsabs'
  robust -- Brigg's robustness parameter
  default=0.0; example: robust=0.5;
  Options: -2.0 to 2.0; -2 (uniform)/+2 (natural)

For weighting='briggsabs'
  noise -- noise parameter to use for Briggs "abs"

weighting
  example noise='1.0mJy'

For superuniform/briggs/briggsabs weighting
  npixels -- number of pixels to determine uv-cell size
            for weight calculation
  example npixels=7

restoringbeam -- Output Gaussian restoring beam for CLEAN image
  [bmaj, bmin, bpa] elliptical Gaussian restoring beam
  default units are in arc-seconds for bmaj,bmin, degrees
  for bpa default: restoringbeam=[]; Use PSF calculated
  from dirty beam.
  example: restoringbeam=['10arcsec'] circular Gaussian
            FWHM 10" example:
            restoringbeam=['10.0','5.0','45.0deg'] 10"x5"
            at 45 degrees

pbcor -- Output primary beam-corrected image
  default: pbcor=False; output un-corrected image
  example: pbcor=True; output pb-corrected image (masked outside
           minpb) Note: if you set pbcor=False, you can later
           recover the pbcor image by dividing by the .flux image
           (e.g. using immath)

minpb -- Minimum PB level to use default=0.1; example:
         minpb=0.01 Note: this minpb is always in effect
         (regardless of pbcor=True/False)

async -- Run asynchronously
  default = False; do not run asynchronously

</example>
H.3.2 File task_clean.py
